(Received 31 May 2002; published 19 August 2002; publisher error corrected 22 August 2002)

We report the observation of a narrow peak in the  $K_S K^- \pi^+$  invariant mass distribution in a sample of exclusive  $B \rightarrow K K_S K^- \pi^+$  decays collected with the Belle detector at the KEKB asymmetric  $e^+ e^-$  collider. The measured mass of the peak is  $M = 3654 \pm 6(\text{stat}) \pm 8(\text{syst}) \text{ MeV}/c^2$ , and we place a 90% confidence level upper limit on the width of  $\Gamma < 55 \text{ MeV}/c^2$ . The properties agree with heavy-quark potential model expectations for the  $\eta_c(2S)$  meson, the  $n = 2$  singlet  $S$  charmonium state.

DOI: 10.1103/PhysRevLett.89.102001

PACS numbers: 14.40.Gx, 12.39.Pn, 13.20.He

Major experimental issues for the charmed-quark anti-charmed-quark ( $c\bar{c}$ ) charmonium particle system are the two  $c\bar{c}$  states that are expected to be below open charm threshold but are still not well established: the radially excited  $n = 2$  singlet  $S$  state, the  $\eta_c(2S)$  meson, and the  $n = 1$  singlet  $P$  state, the  $h_c(1P)$ . The observation of these states and the determination of their masses would complete the below-threshold charmonium particle spectrum and provide useful information about the spin-spin part of the charmonium potential [1].

$B$  meson decays provide an excellent opportunity for searching for the  $\eta_c(2S)$  and clarifying its properties. They are a copious  $\eta_c(1S)$  source: the decays  $B \rightarrow K \eta_c(1S)$  have been observed by CLEO [2], BaBar [3], and Belle [4] with relatively large branching fractions:  $\mathcal{B}[B \rightarrow K \eta_c(1S)] \simeq \mathcal{B}(B \rightarrow K J/\psi) \simeq 1 \times 10^{-3}$ . [In the following, we use  $\eta_c$  to denote the  $\eta_c(1S)$ .] Moreover, in the case of the triplet charmonium  $S$  states,  $B$  meson decays to the radially excited  $\psi(2S)$  are nearly as common as those to the  $n = 1$   $J/\psi$  radial ground state:  $\mathcal{B}[B^+ \rightarrow K^+ \psi(2S)]/\mathcal{B}[B^+ \rightarrow K^+ J/\psi] \sim 0.6$  [5]. Thus, it is reasonable to expect the decays  $B \rightarrow K \eta_c(2S)$  to occur at a rate

comparable to that for  $B \rightarrow K \eta_c$ . Unlike the  $J/\psi$  and  $\psi(2S)$ , where hadronic decays proceed via highly suppressed three-gluon intermediate states, the  $\eta_c$  and  $\eta_c(2S)$  decay via less-suppressed two-gluon processes. As a result, intercharmonium transitions are not very important and the hadronic decay branching fractions for the two states are expected to be similar [6]. Thus, any final state that shows a strong  $B \rightarrow K \eta_c$  signal is a promising channel for an  $\eta_c(2S)$  search.

A simple application of heavy-quark potential models [7] predicts a  $\psi(2S)$ - $\eta_c(2S)$  mass splitting that is smaller than that for the ground-state  $J/\psi$ - $\eta_c$  splitting because of the smaller value of the wave function at zero  $c\bar{c}$  separations and the running of the QCD coupling strength  $\alpha_s(M^2)$ . These models predict an  $\eta_c(2S)$  mass in the range  $3625 < M_{\eta_c(2S)} < 3645 \text{ MeV}/c^2$ . Similar factors result in the expectation that the  $\eta_c(2S)$  total width is somewhat smaller than that of the  $\eta_c$ .

The Crystal Ball group [8] reported an excess of  $E_\gamma \simeq 91 \text{ MeV}$  gamma rays from inclusive  $\psi(2S) \rightarrow \gamma X$  decays and interpreted this as possible evidence for the  $\eta_c(2S)$  with mass  $3594 \pm 5 \text{ MeV}/c^2$ . This result implies a

$\psi(2S) - \eta_c(2S)$  mass splitting that is considerably larger than heavy-quark potential model expectations. The result has not been confirmed by other experiments [9].

In this Letter we report a search for the  $\eta_c(2S)$  produced via the processes  $B^+ \rightarrow K^+ \eta_c(2S)$  and  $B^0 \rightarrow K_S \eta_c(2S)$ , where  $\eta_c(2S) \rightarrow K_S K^- \pi^+$  [10]. We concentrate on this final state because it is a strong decay channel for the  $\eta_c$  ( $\mathcal{B} \simeq 1.8\%$ ), has low combinatorial backgrounds, and, since the final state contains all charged particles, is reconstructed with good resolution. Moreover, the process  $\psi(2S) \rightarrow K_S K^- \pi^+$  is strongly suppressed, and the background in this channel from  $B \rightarrow K \psi(2S)$  decays is expected to be less than 0.1 events.

The search uses a  $41.8 \text{ fb}^{-1}$  data sample collected with the Belle detector [11] at the KEKB  $e^+e^-$  collider [12] operating at the  $Y(4S)$  resonance ( $\sqrt{s} = 10.58 \text{ GeV}$ ). The data sample contains  $44.8 \times 10^6 B\bar{B}$  meson pairs.

The Belle detector is a large-solid-angle magnetic spectrometer that consists of a three-layer silicon vertex detector, a 50-layer central drift chamber (CDC), an array of aerogel threshold Čerenkov counters (ACC), a barrel-like arrangement of time-of-flight (TOF) scintillation counters, and an electromagnetic calorimeter comprised of CsI(Tl) crystals located inside a superconducting solenoid coil that provides a 1.5 T magnetic field. An iron flux return located outside of the coil is instrumented to detect  $K_L$  mesons and to identify muons. The detector is described in detail elsewhere [11].

We select events with  $K^+ K_S K^\pm \pi^\mp$  or  $K_S K_S K^\pm \pi^\mp$  combinations. Here the charged kaon (pion) tracks are required to originate from within  $\delta r < 0.3 \text{ cm}$  and  $|\delta z| < 2.2 \text{ cm}$  of the run-by-run determined interaction point (IP) in the transverse ( $r\phi$ ) and beam line ( $z$ ) directions, respectively. In addition, they must be positively identified as kaons (pions) by the combined information from the ACC, TOF, and CDC  $dE/dx$  measurement. Candidate  $K_S \rightarrow \pi^+ \pi^-$  decays correspond to pairs of oppositely charged tracks with invariant mass within  $12 \text{ MeV}/c^2$  ( $3\sigma$ ) of  $M_{K^0}$  that originate from a common vertex that is displaced by more than 0.3 cm from the IP. The direction of the  $K_S$  momentum vector is required to be within 0.2 rad of the direction between the IP and the position of the displaced vertex.

Candidate  $B$  mesons are reconstructed using the energy difference  $\Delta E \equiv E_B^{\text{cms}} - E_{\text{beam}}^{\text{cms}}$  and the beam-energy constrained mass  $M_{\text{bc}} \equiv \sqrt{(E_{\text{beam}}^{\text{cms}})^2 - (p_B^{\text{cms}})^2}$ , where  $E_{\text{beam}}^{\text{cms}}$  is the center of mass (cms) beam energy, and  $E_B^{\text{cms}}$  and  $p_B^{\text{cms}}$  are, respectively, the cms energy and momentum of the  $B$  candidate. The signal region is defined as  $5.271 < M_{\text{bc}} < 5.287 \text{ GeV}/c^2$  and  $|\Delta E| < 0.040 \text{ GeV}$ , which correspond to  $\pm 3\sigma$  from the central values for both quantities.

In order to suppress background from the  $e^+e^- \rightarrow q\bar{q}$  continuum ( $q = u, d, s$ , and  $c$ ), we form a likelihood ratio from two variables. One is a Fisher discriminant deter-

mined from five modified Fox-Wolfram moments [13], the cosine of the angle formed by the thrust axis of the candidate  $B \rightarrow KK_S K^- \pi^+$  tracks and that of the remaining tracks in the event, and the sum of the absolute values of transverse momenta of particles relative to the  $B$  candidate's thrust axis with angle larger than  $60^\circ$  normalized by the sum of the total momenta. The coefficients of the Fisher discriminant are chosen to optimize the separation between signal and continuum Monte Carlo (MC) events [14]. The other is the cosine of the angle between the  $B$  candidate flight direction and the beam axis in the  $Y(4S)$  rest frame ( $\cos\theta_B$ ). Normalized probability density functions (pdfs) formed from the Fisher discriminant and the  $\cos\theta_B$  distribution are multiplied to form likelihood functions for the signal ( $\mathcal{L}_{\text{sig}}$ ) and continuum ( $\mathcal{L}_{\text{cont}}$ ) processes. We select events with a likelihood ratio  $LR \equiv \mathcal{L}_{\text{sig}} / (\mathcal{L}_{\text{sig}} + \mathcal{L}_{\text{cont}}) > 0.6$ , which was determined by optimizing  $S/\sqrt{S+B}$  ( $S$  and  $B$  are signal and background, respectively,) for Monte Carlo simulations of the process  $B \rightarrow K \eta_c$ , where  $\eta_c \rightarrow K_S K^- \pi^+$ .

We reduce potential backgrounds from  $B \rightarrow D(D_s)X$  decays by rejecting  $D$  and  $D_s$  mesons with the requirements  $|M_{K\pi} - M_D| > 10 \text{ MeV}/c^2$  and  $|M_{K_S K^+} - M_{D_s}| > 10 \text{ MeV}/c^2$ . The decay  $\eta_c(nS) \rightarrow K^*(890)K$  is suppressed by an angular momentum barrier; in order to reduce backgrounds from other  $B$  meson decay modes with minimal loss in signal, we reject events with a  $K^*$  candidate with the requirement  $|M_{K\pi} - M_{K^*}| > 50 \text{ MeV}/c^2$ .

Figure 1 shows the  $M_{\text{bc}}$  projections of events in the  $|\Delta E| \leq 0.040 \text{ GeV}$  signal region for 25  $M_{K_S K\pi}$  mass bins, each  $40 \text{ MeV}/c^2$  wide and with central values

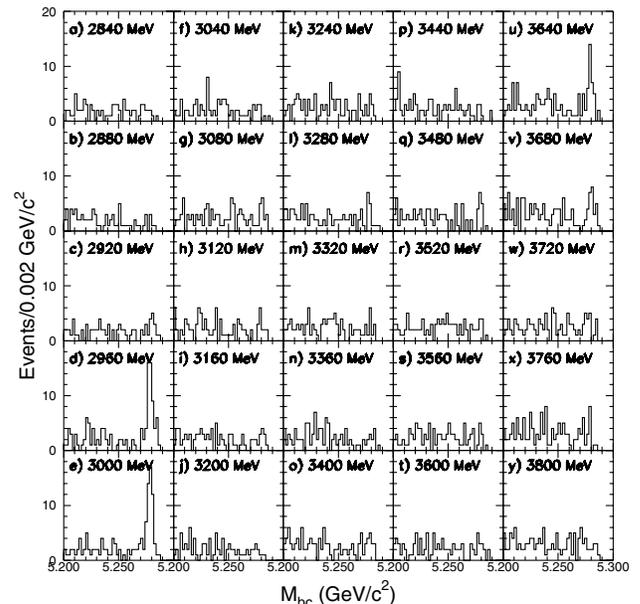

FIG. 1. The  $M_{\text{bc}}$  projections for 40  $\text{MeV}/c^2$  bins of  $M_{K_S K\pi}$ , with central values ranging from 2840 (a) to 3800  $\text{MeV}/c^2$  (y). Only events with  $|\Delta E| < 40 \text{ MeV}$  are included; the charged and neutral  $B$  decay modes are combined.

ranging from 2840 through 3800  $\text{MeV}/c^2$ . The mass bins of Figs. 1(d) and 1(e) straddle  $M_{\eta_c}$  and clear peaks corresponding to  $B \rightarrow K\eta_c$ ,  $\eta_c \rightarrow K_S K^- \pi^+$  decays are apparent. Figures 1(u) and 1(v), which cover a region near the expected mass of the  $\eta_c(2S)$ , also show distinct  $B$  meson signals.

We perform simultaneous fits to each of the  $M_{bc}$  distributions of Fig. 1 and the corresponding  $\Delta E$  distributions for events in the  $M_{bc}$  signal region (not shown). The fits use Gaussian functions with MC-determined widths to represent the signals; the areas of the  $M_{bc}$  and  $\Delta E$  signal functions are constrained to be equal. The  $M_{bc}$  background is modeled by a smooth function that behaves like phase space near the kinematic end point [15]; for the  $\Delta E$  background, we use a second-order polynomial. As an example, the results of the fit to the  $M_{bc}$  and  $\Delta E$  distributions of the  $M_{K_S K \pi} = 3640 \text{ MeV}/c^2$  bin are shown in Figs. 2(a) and 2(b), respectively.

The signal yields extracted from the simultaneous fits to the different  $K_S K^- \pi^+$  mass bins are plotted vs  $M_{K_S K \pi}$  in Fig. 3, where, in addition to a prominent  $\eta_c$  peak, a clear peak at higher mass is evident. We identify this as a candidate for the  $\eta_c(2S)$ . Between the peaks is a nonzero, nonresonant contribution. The curve in Fig. 3 is the result of a fit with simple Breit-Wigner functions to represent the  $\eta_c$  and candidate  $\eta_c(2S)$ , and a second-order polynomial to represent the nonresonant contribution. These functions are convolved with a Gaussian resolution function with a MC-determined width of  $\sigma = 15 \text{ MeV}/c^2$ .

The fit values for the event yields, masses, and total widths of the  $\eta_c$  and the  $\eta_c(2S)$  candidate state are listed with their statistical errors in Table I. The fit value for the  $\eta_c$  mass is in good agreement with the world-average value of  $M_{\eta_c} = 2979.8 \pm 1.8 \text{ MeV}/c^2$  [5]; the value for the  $\eta_c$  width is consistent, within its rather large errors, both with the existing world average of  $\Gamma_{\eta_c}^{\text{tot}} = 13.2^{+3.8}_{-3.2} \text{ MeV}/c^2$  [5] and the recent CLEO result of  $26 \pm 6 \text{ MeV}/c^2$  [16].

The sum of the observed events in the three mass bins in the signal region [i.e., centered around  $M(K_S K \pi) = 3640 \text{ MeV}/c^2$ ] is 56, while the integral of the second-order

polynomial over the same interval gives a nonresonant expectation of  $21 \pm 2$  events. The probability for this to fluctuate up to 56 events is  $\sim 10^{-8}$ , which corresponds to a signal significance of more than  $6\sigma$ .

The fitted mass of the candidate  $\eta_c(2S)$  is substantially above the Crystal Ball mass value and consistent, within errors, with the upper end of potential model expectations. The systematic error on the mass is evaluated by redoing the analysis using different likelihood ratio selection requirements, 50  $\text{MeV}/c^2$ -wide bins, bins with central values shifted by half a bin width, and with different values of the experimental resolution. The maximum change in the fitted mass value is  $8 \text{ MeV}/c^2$ , which is taken as the systematic error. The limited statistics and the resolution precludes a precise measurement of the width. However, we can establish a 90% confidence level upper limit of  $\Gamma < 55 \text{ MeV}/c^2$ .

Monte Carlo simulations indicate that the acceptance is very nearly constant over the  $K_S K^- \pi^+$  mass region covered by this measurement [17]. Thus, the ratio of product branching fractions for the  $\eta_c$  and  $\eta_c(2S)$  is just the ratio of event yields:

$$\frac{\mathcal{B}[B \rightarrow K\eta_c(2S)]\mathcal{B}[\eta_c(2S) \rightarrow K_S K^- \pi^+]}{\mathcal{B}(B \rightarrow K\eta_c)\mathcal{B}(\eta_c \rightarrow K_S K^- \pi^+)} = 0.38 \pm 0.12 \pm 0.05, \quad (1)$$

where the first error is statistical and the second systematic. The systematic error is determined from changes in the ratio observed for different binning, values of resolution, and functions used to model the nonresonant contribution.

In summary, we observe a peak in the  $K_S K^- \pi^+$  mass from exclusive  $B^+ \rightarrow K^+ K_S K^- \pi^+$  and  $B^0 \rightarrow K_S K_S K^- \pi^+$  decays with mass and width values

$$M = 3654 \pm 6 \pm 8 \text{ MeV}/c^2, \quad \Gamma < 55 \text{ MeV}/c^2;$$

these are consistent with expectations for the  $B \rightarrow K\eta_c(2S)$ , where  $\eta_c(2S) \rightarrow K_S K^- \pi^+$ . In addition, the product branching fraction is comparable in magnitude to that for the  $\eta_c$ , also in agreement with expectations for the

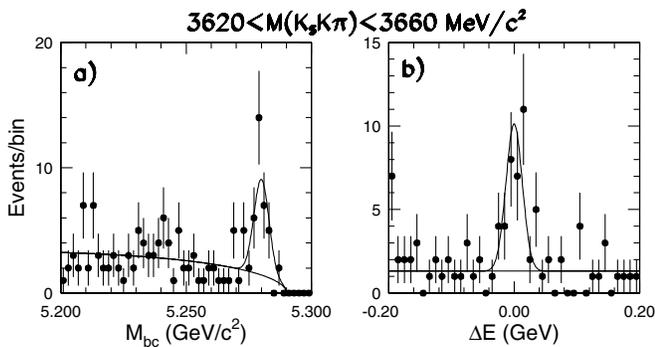

FIG. 2. The (a)  $M_{bc}$  and (b)  $\Delta E$  projections for the  $M_{K_S K \pi} = 3640 \text{ MeV}/c^2$  mass bin. The curves are the results of the simultaneous fit described in the text.

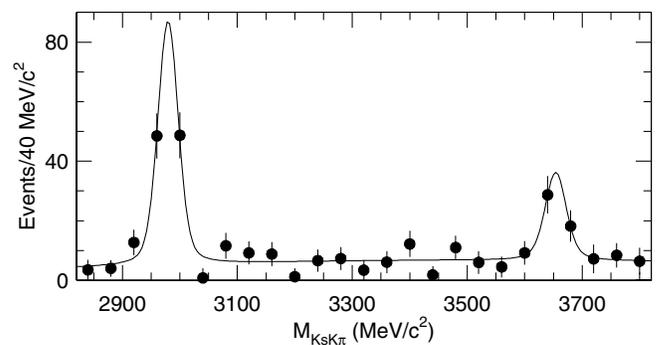

FIG. 3. The distribution of signal events from the simultaneous fits to  $M_{bc}$  and  $\Delta E$  for each  $K_S K \pi$  mass bin. The curve is the result of the fit described in the text.

TABLE I. Results of the fit to the data points in Fig. 3. Only statistical errors are listed.

Peak	Events	Mass (MeV/ $c^2$ )	$\Gamma^{\text{tot}}$ (MeV/ $c^2$ )
$\eta_c$	$104 \pm 14$	$2979 \pm 2$	$11 \pm 11$
$\eta_c(2S)$	$39 \pm 11$	$3654 \pm 6$	$15^{+24}_{-15}$

$\eta_c(2S)$ . The observed properties of this system lead us to conclude that we have observed the  $\eta_c(2S)$ .
