The inclusive spectrum of $B \to J/\psi + X$ has been studied extensively and is consistent with the prediction of nonrelativistic QCD calculations [1], except for an excess in the low momentum region [2,3]. This momentum region corresponds to the $J/\psi$ meson recoiling against particle systems with an invariant mass of $\sim 2$ GeV/$c^2$. The observed excess below 0.8 GeV/$c$ corresponds to a branching fraction of a few times $10^{-4}$.

Several hypotheses [4–6] have been proposed to explain this excess. One of the decay modes proposed in Ref. [4], $B^+ \to J/\psi \Lambda \bar{\Phi}$ [7], has been studied by BABAR [8] and Belle [9]. The measured branching fraction, of order $10^{-5}$, is too small to account for the excess.

Chang and Hou [5] proposed intrinsic charm ($c\bar{c}$) in the $B$ meson as an explanation. The intrinsic charm pair transforms into a $c\bar{c}$ final state when the $B$ meson decays. The most promising decay modes are $B^0(d\bar{c}c\bar{c}) \to J/\psi D^0\pi^0$ and $B^+(u\bar{c}c\bar{c}) \to J/\psi D^0\pi^+$. According to this hypothesis, if the intrinsic charm content of the $B$ is not much less than 1%, the branching fractions of the above decay modes could be $\sim 10^{-4}$, while the prediction from the standard QCD framework is of order $10^{-8}$ [6].

In this paper, we report on a search for the decay modes $B^0 \to J/\psi D^0$ and $B^+ \to J/\psi D^0\pi^+$. The analysis is based on a data sample of 140 fb$^{-1}$, which contains $152 \times 10^6 B\bar{B}$ pairs, accumulated at the $\Upsilon(4S)$ resonance with the Belle detector [10] at the KEKB 8 GeV $e^+e^-$ and 3.5 GeV $e^+e^-$ asymmetric collider [11].

The Belle detector is a large-solid-angle magnetic spectrometer that consists of a three-layer silicon vertex detector (SVD), a 50-layer central drift chamber (CDC), an array of aerogel threshold Čerenkov counters (ACC), a barrel-like arrangement of time-of-flight scintillation counters (TOF), and an electromagnetic calorimeter comprised of CsI(Tl) crystals (ECL). These detectors are located inside a superconducting solenoid coil that provides a 1.5 T magnetic field. An iron flux-return located outside of the coil is instrumented to detect $K_L$ mesons and to identify muons (KLM).

Events are required to pass the hadronic event selection criteria [12]. To suppress continuum backgrounds ($e^+e^- \to q\bar{q}$, where $q = u, d, s, c$), we require $R_2 < 0.5$, where $R_2$ is the ratio of the second to zeroth Fox-Wolfram moments [13].

The selection criteria for $J/\psi$ mesons decaying to $l^+l^-$ (where $l = e, \mu$) are identical to those used in Ref. [9,12]. To remove charged particle tracks that do not come from the interaction region, we require that the leptons originate from within 5 cm of the nominal interaction point (IP) along the beam direction. Both tracks are required to be positively identified as leptons. In order to reduce the effect of bremsstrahlung or final state radiation, clusters detected in the ECL within 0.05 radians of the original $e^-$ or $e^+$ direction are added in the invariant mass calculation. The $J/\psi$ candidate is required to satisfy an asymmetric invariant mass requirement that takes account of the radiative tail: $-150(\sim 60) < (M_{e^+e^-})_0 - m_{J/\psi} < 36(36)$ MeV/$c^2$, where $m_{J/\psi}$ is the nominal $J/\psi$ mass.
SEARCH FOR $B^0 \rightarrow J/\psi \bar{D}^0$ AND $B^+ \rightarrow J/\psi D^0 \pi^+$ DECAYS

[14]. In order to improve the momentum resolution, vertex and mass constrained fits are then applied to the $J/\psi$ candidates that pass the above selection criteria.

For charged pion and kaon identification, the specific ionization $(dE/dx)$ in the CDC, the flight time measured in the TOF, and the response of the ACC are combined into a likelihood $L_h$, where $h$ stands for the hadron type ($\pi$, $K$, $p$). A track is labeled as a kaon if $L_K/(L_K + L_\pi) > 0.5$ or a pion if $L_\pi/(L_\pi + L_K) > 0.3$; the respective efficiencies are 90% and 92%, while the respective $\pi/K$ misidentification rates are 10% and 13%. Tracks in the kaon sample with $L_p/(L_p + L_K) > 0.99$ are reclassified as protons and thereby discarded. All tracks positively identified as electrons are rejected.

A $D^0$ meson candidate is reconstructed from a $K^-$ and a $\pi^+$ meson pair. The two tracks must satisfy $dr < 0.3$ cm and $|dz| < 5$ cm, where $dr$ is the impact parameter perpendicular to (along) the beam direction with respect to the IP, determined run-by-run. We select $D^0$ candidates for further analysis within the mass window $[M_{K\pi} - m_{D^0}] < 150$ MeV/$c^2$, where $m_{D^0}$ is the nominal $D^0$ mass [14]. We also apply a vertex constrained fit to the $D^0$ candidates.

For the charged pion in $B^+ \rightarrow J/\psi \bar{D}^0 \pi^+$, we apply the requirements with looser $dr < 0.6$ cm, $|dz| < 5$ cm, and tighter $L_\pi/(L_\pi + L_K) > 0.9$ due to its low momentum.

$B$ mesons are reconstructed by combining a $J/\psi$ and a $D^0$ candidate for $B^0 \rightarrow J/\psi \bar{D}^0$, and an additional pion with the same charge as the kaon from $D^0$ for $B^+ \rightarrow J/\psi D^0 \pi^+$. To reduce combinatorial background, we impose a requirement on the vertex quality ($\chi^2$) of the vertex fit for the leptons from $J/\psi$ and the $D^0$ trajectory (and the $\pi^+$ for the $B^+$ case). The vertexing requirement retains 94% (78%) of the $B^0$ ($B^+$) signal.

We reject $B^+ \rightarrow \psi(2S)K^+ [\psi(2S) \rightarrow J/\psi \pi^+ \pi^-]$ decay by requiring $M_{\gamma\gamma}(\gamma) \pi^+ \pi^- - M_{\gamma\gamma}(\gamma)$ to be outside of the $\pm15$ MeV/$c^2$ window around the nominal mass difference between $\psi(2S)$ and $J/\psi$. We require $|\cos\theta_B| < 0.8$ to further suppress combinatorial background, where $\theta_B$ is the angle between the $B$ flight direction and positron beam direction in the center-of-mass (cms) frame.

We select $B$ candidates by requiring that the beam-energy constrained mass $(M_{bc} = \sqrt{E_{\text{beam}}^2 - P_b^2})$ and the mass difference $(\Delta M_B \equiv M_B - m_B)$ [15] lie within the region $M_{bc} > 5.2$ GeV/$c^2$ and $-0.3 < \Delta M_B < 0.2$ GeV/$c^2$; here, $E_{\text{beam}}$ and $P_b$ are the beam energy and $B$ momentum in the cms, while $M_B$ and $m_B$ are the reconstructed and the nominal mass of the $B$ meson. The signal region for $B^0$ ($B^+$) candidates is defined as $5.27 < M_{bc} < 5.29$ GeV/$c^2$, $|\Delta M_B| < 19.0(17.1)$ MeV/$c^2$, $|M_{K\pi} - m_{D^0}| < 16.5$ MeV/$c^2$, corresponding to 3 standard deviation windows based on Monte Carlo (MC) simulation and the data control samples described later. The candidates outside of the signal region are used to determine the background components in the fit described below.

After the selection, around 3.6% (42%) of $B^0$ ($B^+$) candidate events have more than one $B$ candidate. In multiple candidate cases, we select the candidate with the best vertex fit quality.

Background is divided into categories that have distinct shapes in the $(M_{bc}, \Delta M_B, M_{K\pi})$ distributions: nonresonant background, two types of combinatorial backgrounds, and peaking backgrounds. In the case of nonresonant background, a $B$ meson decays to the signal final state, but the $K^+$ and $\pi^-$ mesons do not come from a $D^0$ decay. In the case of combinatorial background, the reconstructed $J/\psi$ and $D^0$ [and a pion, for a $B^+$ candidate] come from different $B$ mesons (90% of the time) or from continuum events (10%). No peak appears in the $(M_{bc}, \Delta M_B)$ distribution; however, one subclass—$c$mb(D0)—has a peak in the $M_{K\pi}$ distribution ($D^0$ correctly reconstructed), while the other—$c$mb(fake D0)—does not (fake $D^0$).

The peaking background shows an enhancement in the $M_{K\pi}$ signal region. For the $B^0 \rightarrow J/\psi \bar{D}^0$ signal, one source of this background is from $B^+ \rightarrow \psi(2S)(\chi)K^+$ decay, where the $J/\psi$ and $K^+$ are combined with a pion from the $B^-$ meson. Another source is from $B^+ \rightarrow J/\psi K^+ \pi^- \pi^+$ ($B^0 \rightarrow J/\psi K^+ \pi^- \pi^0$) decay where the second pion is missed. For the $B^+ \rightarrow J/\psi \bar{D}^0 \pi^+$ signal, one source of peaking background comes from the aforementioned $B^+ (B^0)$ decay with the $\pi^+$ ($\pi^0$) replaced by a charged pion from the other $B$ meson. Another is from the $B^0 \rightarrow J/\psi K^- \pi^- \pi^+$ decay combined with a $\pi^+$ from the accompanying $B$. For the $B^0$ ($B^+$) signal, the first-mentioned peaking background distributes broadly around the $\Delta M_B$ signal region, while the second exhibits a narrow peak shifted to negative (positive) values by a pion mass. The narrow peak is excluded by limiting the fit region to $\Delta M_B > -0.12(< +0.12)$ GeV/$c^2$.

The yields are extracted by maximizing the three-dimensional (3D) extended likelihood function,

$$L = \frac{e^{-\sum N_i}}{N!} \prod_{i=1}^{N} \sum_{k} N_k P_k (M_{bc}, \Delta M^i_B, M_{K\pi})$$

where $N$ is the total number of candidate events, $i$ is the identifier of the $i$-th event, $N_k$ and $P_k$ are the yield and probability density function (PDF) of component $k$, which corresponds to the signal and each aforementioned background.

The signal PDF is determined using MC simulation and control-sample data. A Gaussian is used as the $M_{bc}$ PDF. Since $\Delta M_B$ is correlated with $M_{K\pi}$ but not with $\Delta M_B - M_{K\pi}$, we use the product of the $M_{K\pi}$ and $\Delta M_B - M_{K\pi}$ PDFs, each of which is the sum of two Gaussians. The parameters of the $M_{K\pi}$ PDF are extracted from the inclusive $D^0$ data sample with cms momentum less than 1.5 GeV/$c$, using the same $D^0$ selection criteria as those for $B$ decays. The mean and width of the $M_{bc}$ PDF and the main Gaussian of the $\Delta M_B$ PDF (integrated over $M_{K\pi}$) are
calibrated using a $B^0 \rightarrow J/\psi K^{*0}(K^{*0} \rightarrow K^+ \pi^-)$ control sample.

The $B^+ \rightarrow J/\psi \bar{D}^0 \pi^+$ signal PDF has an additional
component where a low momentum pion is incorrectly assigned as the pion from $B$ decay. We construct its PDF
from the product of the double-Gaussian in $M_{K\pi}$ with a
two-dimensional (2D) smoothed histogram in $M_{bc}$ and
$\Delta M_B$. The fraction of this component is estimated to be
$(37.4 \pm 0.7\%)$ from signal MC and is fixed in the fit.

For nonresonant background, the $M_{bc}$ and $\Delta M_B$ PDFs
are taken to be the same as the signal PDFs integrated over
$M_{K\pi}$, while a second-order polynomial is used for the $M_{K\pi}$
PDF. For combinatorial background, a threshold function
[16] is used for the $M_{bc}$ PDF. For $B^0 \rightarrow J/\psi \bar{D}^0$, a first-
order polynomial is used for the $\Delta M_B$ PDF. To take into
account the kinematic boundary for $B^+ \rightarrow J/\psi \bar{D}^0 \pi^+$, we
use another threshold function,

$$P_{\text{thr}}(x_c, x_c; p, c) = \begin{cases} 
(x - x_c)^p e^{-c(x - x_c)} & (x \geq x_c) \\
0 & (x < x_c)
\end{cases}$$

with $x = \Delta M_B$ and $x_c = M_{K\pi} - (m_{B^+} - m_{J/\psi} - m_{\pi^+})$,
where $m_{B^+}$ and $m_{\pi^+}$ are the nominal $B^+$ and $\pi^+$ masses.
The same $M_{K\pi}$ PDF as used for signal is used for cmb(D0),
while a first-order polynomial is used for cmb(fake D0).
For peaking backgrounds, the PDFs are modeled by 3D
smoothed histograms from a large $J/\psi$ inclusive MC
sample.

In the fit, the value of $N_{i_k}$ and the parameters for the
polynomials and threshold functions are allowed to float.

Figure 1 shows ($M_{K\pi}, \Delta M_B$) scatter plots for candidates
in the $M_{bc}$ signal region. There are 11 candidates in the
signal region for $B^0 \rightarrow J/\psi \bar{D}^0$ and one for $B^+ \rightarrow J/\psi \bar{D}^0 \pi^+$. Table I summarizes the results. The signal
yields ($Y$) in the signal box, the expected total background
yields ($b$), and their statistical errors are obtained from the
maximum likelihood fit. The efficiencies ($\epsilon$) are deter-
mimed from the signal MC sample with the same event
selection used for the data. A three-body phase-space
model is employed for $B^+ \rightarrow J/\psi \bar{D}^0 \pi^+$ decay. The
$\Delta M_B$, $M_{K\pi}$, and $M_{bc}$ distributions are plotted in Fig. 2.
Also shown are projections of the maximum likelihood fit
result, which agree well with the data. No significant
signals are found. We determine 90% C.L. upper limits
for the signal yield ($Y_{90}$) and branching fraction ($B$) from
the observed number of candidates ($n_0$) and the estimated
backgrounds ($b$) in the signal box using the Feldman-
Cousins method [17]. The systematic errors due to the
uncertainties of signal detection efficiency and background
yield, elucidated below, are taken into account [18]. The
decay branching fractions $B(J/\psi \rightarrow l^+ l^-)$ and $B(D^0 \rightarrow
K^- \pi^+)$ are taken from the world averages [14]. The fractions
of neutral and charged $B$ mesons produced in $Y(4S)$
decays are assumed to be equal.

The systematic errors on the background yields are evaluated by varying each fixed PDF parameter by $\pm 1\sigma$ of the measured error, by increasing the order of polynomial
for combinatorial background, and by changing the
$M_{K\pi}$ PDF of nonresonant background to an exponential
function. The changes in the background yields induced by
individual variations are added in quadrature. The system-
atic errors for the efficiency (Table II) consist of the
uncertainties in tracking efficiency of
$M_{bc}$ and $\Delta M_B$ for the
signal box, and in MC statistics of

L. M. ZHANG et al.
PHYSICAL REVIEW D 71, 091107 (2005)
FIG. 2. \( \Delta M_B, M_K, \) and \( M_{bc} \) distributions in all or related variables’ signal regions, as labeled inside each plot, for \( B^0 \rightarrow J/\psi \bar{D}^0 \) (top) and \( B^+ \rightarrow J/\psi \bar{D}^0 \pi^+ \) (bottom). Superimposed on the data are projections of the signal and summed background components of the maximum likelihood fit result.

1.2%. For \( B^+ \rightarrow J/\psi \bar{D}^0 \pi^+ \) decay, an additional systematic error of \(+13.7\% / -38.3\%\) due to the three-body phase-space model is assigned to the maximum efficiency variation among the slices of \( M(J/\psi, \bar{D}^0), M(J/\psi, \pi^+) \) and \( M(\bar{D}^0, \pi^+) \).

We also obtain the branching fractions of the corresponding nonresonant decay channels in the \( 1.71 < M_{K^+ \pi^-} < 2.01 \text{ GeV/c}^2 \) region from the yields of the nonresonant components in the fit. The yields in \( \Delta M_B \) and \( M_{bc} \) signal region are \( 80.9^{+10.2}_{-9.5} \) for \( B^0 \rightarrow J/\psi K^+ \pi^- \) and \( 10.1^{+4.0}_{-3.3} \) for \( B^+ \rightarrow J/\psi K^+ \pi^- \pi^+ \). The efficiencies are verified to be the same as for the modes with an intermediate \( D^0 \) resonance. The systematic errors are estimated by the same procedure. In \( B^+ \) decay, we subtract the contribution from \( B^+ \rightarrow X(3872)K^+ [X(3872) \rightarrow J/\psi \pi^+ \pi^-] \), which is estimated to be \( 1.20 \pm 0.33 \) candidates by MC simulation with the branching fraction taken from Ref. [19]. Finally, we obtain \( \mathcal{B}(B^0 \rightarrow J/\psi K^+ \pi^-) = (1.51^{+0.19}_{-0.18} \pm 0.15) \times 10^{-5} \) and \( \mathcal{B}(B^+ \rightarrow J/\psi K^+ \pi^- \pi^+) = (3.3^{+1.6}_{-1.3} \pm 1.6) \times 10^{-6} \) in the limited \( M_{K^+ \pi^-} \) region (where the first errors are stat. and the second are syst.).

In summary, we have performed a search for $B^0 \rightarrow J/\psi \overline{D}^0$ and $B^+ \rightarrow J/\psi \overline{D}^0 \pi^+$ decays. No signal is observed for either decay mode and upper limits on the branching fraction at 90% C.L. are determined to be

$$\mathcal{B}(B^0 \rightarrow J/\psi \overline{D}^0) < 2.0 \times 10^{-5},$$
$$\mathcal{B}(B^+ \rightarrow J/\psi \overline{D}^0 \pi^+) < 2.5 \times 10^{-5}.$$  

The results are consistent with the BABAR results [20] and rule out the explanation of the excess in the low momentum region of the inclusive $J/\psi$ spectrum as intrinsic charm content at the 1% level in the $B$ meson.

We thank the KEKB group for the excellent operation of the accelerator, the KEK cryogenics group for the efficient operation of the solenoid, and the KEK computer group and the NII for valuable computing and Super-SINET network support. We acknowledge support from MEXT and ISPS (Japan); ARC and DEST (Australia); NSFC (contract No. 10175071, China); DST (India); the BK21 program of MOEHRD and the CHEP SRC program of KOSEF (Korea); KBN (contract No. 2P03B 01324, Poland); MIST (Russia); MHEST (Slovenia); SNSF (Switzerland); NSC and MOE (Taiwan); and DOE (USA).

[7] Inclusion of charge conjugate states is implied throughout this paper.
[15] The benefit of using $\Delta M_B$ instead of the energy difference is described in Ref. [9].
