We report measurements of time-dependent decay rates for $B^{0} \rightarrow D^{(*)-} \pi^{+}$decays and extraction of $C P$ violation parameters that depend on $\phi_{3}$. Using fully reconstructed $D^{(*)} \pi$ events and partially reconstructed $D^{*} \pi$ events from a data sample that contains $386 \times 10^{6} B \bar{B}$ pairs that was collected near the $\mathrm{Y}(4 S)$ resonance, with the Belle detector at the KEKB asymmetric energy $e^{+} e^{-}$collider, we obtain the $C P$ violation parameters $S^{+}\left(D^{(*)} \pi\right)$ and $S^{-}\left(D^{(*)} \pi\right)$. We obtain $S^{+}\left(D^{*} \pi\right)=0.049 \pm 0.020$ (stat) $\pm$ $0.011(\mathrm{sys}), \quad S^{-}\left(D^{*} \pi\right)=0.031 \pm 0.019($ stat $) \pm 0.011(\mathrm{sys}), \quad$ and $\quad S^{+}(D \pi)=0.031 \pm 0.030($ stat $) \pm$ 0.012 (sys), $S^{-}(D \pi)=0.068 \pm 0.029$ (stat) $\pm 0.012$ (sys). These results are an indication of $C P$ violation in $B^{0} \rightarrow D^{*-} \pi^{+}$and $B^{0} \rightarrow D^{-} \pi^{+}$decays at the $2.5 \sigma$ and $2.2 \sigma$ levels, respectively. If we use the values of $R_{D^{(*)} \pi}$ that are derived using assumptions of factorization and $\mathrm{SU}(3)$ symmetry, branching fraction measurements for the $B \rightarrow D_{s}^{(*)} \pi$ modes, and lattice QCD calculations, we can restrict the allowed region of $\left|\sin \left(2 \phi_{1}+\phi_{3}\right)\right|$ to be above 0.44 and 0.52 at $68 \%$ confidence level from the $D^{*} \pi$ and $D \pi$ modes, respectively.

## I. INTRODUCTION

Within the standard model (SM), $C P$ violation arises due to a single phase in the Cabibbo-Kobayashi-Maskawa (CKM) quark mixing matrix [1]. Precise measurements of CKM matrix parameters therefore constrain the SM, and may reveal new sources of $C P$ violation. Measurements of the time-dependent decay rates of $B^{0}\left(\bar{B}^{0}\right) \rightarrow D^{(*) \mp} \pi^{ \pm}$
provide a theoretically clean method for extracting $\sin \left(2 \phi_{1}+\phi_{3}\right)$ [2]. As shown in Fig. 1, these decays can be mediated by both Cabibbo-favored decay (CFD) and doubly-Cabibbo-suppressed decay (DCSD) amplitudes, $V_{c b}^{*} V_{u d}$ and $V_{u b}^{*} V_{c d}$, which have a relative weak phase $\phi_{3}$.

The time-dependent decay rates are given by [3]

$$
\begin{align*}
& P\left(B^{0} \rightarrow D^{(*)+} \pi^{-}\right)=\frac{1}{8 \tau_{B^{0}}} e^{-|\Delta t| / \tau_{B^{0}}}\left[1-C \cos (\Delta m \Delta t)-S^{+} \sin (\Delta m \Delta t)\right], \\
& P\left(B^{0} \rightarrow D^{(*)-} \pi^{+}\right)=\frac{1}{8 \tau_{B^{0}}} e^{-|\Delta t| / \tau_{B^{0}}}\left[1+C \cos (\Delta m \Delta t)-S^{-} \sin (\Delta m \Delta t)\right], \\
& P\left(\bar{B}^{0} \rightarrow D^{(*)+} \pi^{-}\right)=\frac{1}{8 \tau_{B^{0}}} e^{-|\Delta t| / \tau_{B^{0}}}\left[1+C \cos (\Delta m \Delta t)+S^{+} \sin (\Delta m \Delta t)\right],  \tag{1}\\
& P\left(\bar{B}^{0} \rightarrow D^{(*)-} \pi^{+}\right)=\frac{1}{8 \tau_{B^{0}}} e^{-|\Delta t| / \tau_{B^{0}}}\left[1-C \cos (\Delta m \Delta t)+S^{-} \sin (\Delta m \Delta t)\right] .
\end{align*}
$$

Here $\Delta t$ is the difference between the time of the decay and the time that the flavor of the $B$ meson is tagged, $\tau_{B^{0}}$ is the average neutral $B$ meson lifetime, $\Delta m$ is the $B^{0}-\bar{B}^{0}$ mixing parameter, and $C=\left(1-R^{2}\right) /\left(1+R^{2}\right)$, where $R$ is the ratio of the magnitudes of the DCSD and CFD (we assume the magnitudes of both the CFD and DCSD amplitudes are the same for

FIG. 1. Diagrams for (a) $B^{0} \rightarrow D^{(*)-} \pi^{+}$and (b) $\bar{B}^{0} \rightarrow D^{(*)-} \pi^{+}$. Those for $\bar{B}^{0} \rightarrow D^{(*)+} \boldsymbol{\pi}^{-}$and $B^{0} \rightarrow D^{(*)+} \pi^{-}$can be obtained by charge conjugation.
$B^{0}$ and $\bar{B}^{0}$ decays). The $C P$ violation parameters are given by

$$
\begin{equation*}
S^{ \pm}=\frac{2(-1)^{L} R \sin \left(2 \phi_{1}+\phi_{3} \pm \delta\right)}{\left(1+R^{2}\right)} \tag{2}
\end{equation*}
$$

where $L$ is the orbital angular momentum of the final state ( 1 for $D^{*} \pi$ and 0 for $D \pi$ ), and $\delta$ is the strong phase difference of the CFD and DCSD. The values of $R$ and $\delta$ are not necessarily the same for $D^{*} \pi$ and $D \pi$ final states, and are denoted with subscripts, $D^{*} \pi$ and $D \pi$, in what follows.

Although not measured yet, the value of $R$ is predicted to be about 0.02 [4]. Therefore, we neglect terms of $\mathcal{O}\left(R^{2}\right)$ (and hence take $C=1$ ). There are theoretical arguments that the still unmeasured values of $\delta$ for both $D^{*} \pi$ and $D \pi$ are small $[3,5]$.

Because of the size of $R, C P$ violation is expected to be a small effect in these decays. Therefore, a large event sample is needed in order to obtain sufficient sensitivity. With this in mind, we employ a partial reconstruction technique [6] for the $D^{*} \pi$ analysis in addition to the conventional full reconstruction method. In this approach, the signal is distinguished from the background on the basis of kinematics of the "fast" pion from the decay $B \rightarrow$ $D^{*} \pi_{f}$, and the "slow" pion from the decay $D^{*} \rightarrow D \pi_{s}$, alone; no attempt is made to reconstruct the $D$ meson from its decay products. Background from continuum $e^{+} e^{-} \rightarrow$ $q \bar{q}(q=u, d, s, c)$ events is reduced dramatically by requiring the presence of a high-momentum lepton in the event, which also serves to tag the flavor of the associated $B$ in the event.

Results from our previous analyses using a $140 \mathrm{fb}^{-1}$ data sample containing $152 \times 10^{6} B \bar{B}$ pairs have been published for the full reconstruction method [7] and the partial reconstruction method [8]. Results from similar analyses by the $B A B A R$ collaboration were also reported [ 9,10$]$. This study is a continuation of similar analyses with a substantially increased data sample containing $386 \times 10^{6}$ $B \bar{B}$ events, and several improvements in the analyses.

## II. BELLE DETECTOR

The data was collected with the Belle detector [11] at the KEKB asymmetric energy electron-positron collider [12] operating at the $Y(4 \mathrm{~S})$ resonance. The Belle detector is a
large-solid-angle magnetic spectrometer that consists of a silicon vertex detector (SVD), a 50-layer central drift chamber (CDC), an array of aerogel threshold Cherenkov counters (ACC), a barrel-like arrangement of time-of-flight scintillation counters (TOF), and an electromagnetic calorimeter (ECL) comprised of $\mathrm{CsI}(\mathrm{Tl})$ crystals located inside a superconducting solenoidal coil that provides a 1.5 T magnetic field. An iron flux-return located outside of the coil is instrumented to detect $K_{L}^{0}$ mesons and to identify muons (KLM). A sample containing $152 \times 10^{6} B \bar{B}$ pairs was collected with a 2.0 cm radius beampipe and a 3-layer silicon vertex detector (SVD1), while a sample of $234 \times$ $10^{6} B \bar{B}$ pairs was collected with a 1.5 cm radius beampipe, a 4-layer silicon detector, and a small-cell inner drift chamber (SVD2) [13].

## III. FULL RECONSTRUCTION ANALYSIS

## A. Signal event selection

The selection of hadronic events is described elsewhere [14]. For the $\bar{B}^{0} \rightarrow D^{*+} \pi^{-}$event selection, we use the decay chain $D^{*+} \rightarrow D^{+} \pi^{0}$ or $D^{0} \pi^{+}$with subsequent decays of $D^{+} \rightarrow K^{-} \pi^{+} \pi^{+}$and $D^{0} \rightarrow K^{-} \pi^{+}, K^{-} \pi^{+} \pi^{0}$, $K^{-} \pi^{+} \pi^{+} \pi^{-}, K_{S}^{0} \pi^{+} \pi^{-}\left(K_{S}^{0} \rightarrow \pi^{+} \pi^{-}\right)$. (Charge conjugate modes are implied throughout this paper.) All charged tracks except for the slow pions from $D^{*} \rightarrow D \pi$ decays are required to have a minimum of one hit (two hits) in the $r-\phi$ $(z)$ coordinate of the vertex detector, where the $r-\phi$ plane is transverse to the positron beam line that defines the $z$ axis. These requirements allow a precise determination of the production point. To separate kaons from pions, we form a likelihood for each track, $\mathcal{L}_{K(\pi)}$. The kaon likelihood ratio, $P(K / \pi)=\mathcal{L}_{K} /\left(\mathcal{L}_{K}+\mathcal{L}_{\pi}\right)$, has values between 0 (likely to be a pion) and 1 (likely to be a kaon). We require charged kaons to satisfy $P(K / \pi)>0.3$, corresponding to about $95 \%$ efficiency for detecting kaons and about $2 \%$ probability for misidentifying pions as kaons. There is no such requirement for charged pions coming from $D$ decays.

Neutral pions are formed from photon pairs with invariant masses between $0.118 \mathrm{GeV} / c^{2}$ and $0.150 \mathrm{GeV} / c^{2}$. The photon momenta are then recalculated with a $\pi^{0}$ mass constraint.

We require the invariant mass of $K_{S}^{0} \rightarrow \pi^{+} \pi^{-}$candidates to be between $0.485 \mathrm{GeV} / c^{2}$ and $0.510 \mathrm{GeV} / c^{2}$
corresponding to $\pm 5 \sigma$, where $\sigma$ is the Monte Carlo (MC) determined invariant mass resolution. The radial impact parameter, which is the distance of closest approach of the candidate charged tracks to the event-dependent interaction point (IP) in the $r-\phi$ plane, is required to be larger than 0.02 cm for high momentum ( $>1.5 \mathrm{GeV} / c$ ) $K_{S}^{0}$ candidates and 0.03 cm for those with momentum less than $1.5 \mathrm{GeV} / c$. Here the IP is determined for each set of 10000 neighboring hadronic events, and the $K_{S}^{0}$ momentum is given in the $\Upsilon(4 \mathrm{~S})$ rest frame (cms). The $\pi^{+} \pi^{-}$ vertex is required to be displaced from the IP by a minimum transverse distance of 0.22 cm for high momentum candidates and 0.08 cm for the remaining candidates. The mismatch in the $z$ direction at the $K_{S}^{0}$ vertex point for the $\pi^{+} \pi^{-}$tracks must be less than 2.4 cm for high momentum candidates and 1.8 cm for the remaining candidates. The direction of the pion pair momentum must also agree with the direction of the vertex point from the IP to within 0.03 rad for high momentum candidates and to within 0.1 rad for the remaining candidates. A mass and vertex constraint is imposed when fitting the $K_{S}^{0}$ candidates.

For $D^{0}$ meson candidates, the invariant mass of the $D^{0}$ candidate is required to be within $\pm 20, \pm 30, \pm 20$, and $\pm 20 \mathrm{MeV} / c^{2}$ for $K^{-} \pi^{+}, \quad K^{-} \pi^{+} \pi^{0}, \quad K^{-} \pi^{+} \pi^{+} \pi^{-}$, $K_{S}^{0} \pi^{+} \pi^{-}$modes, respectively, while the invariant mass of the $D^{+}$candidates should be within $\pm 18 \mathrm{MeV} / c^{2}$ of the nominal $D^{+}$mass corresponding to $\pm 4 \sigma$. For the $D^{0} \rightarrow K^{-} \pi^{+} \pi^{0}$ mode, we further require the $\pi^{0} \mathrm{cms}$ momentum to be greater than $200 \mathrm{MeV} / c$. We use a massand vertex-constrained fit for $D$ candidates.

The $D^{*+}$ is reconstructed by combining either $D^{0}$ candidates with a slow $\pi^{+}$meson, or $D^{+}$candidates with a slow $\pi^{0}$ meson. The $D^{*}$ candidates are required to have a mass difference $\Delta M=M_{D \pi}-M_{D}$ within $\pm 3 \mathrm{MeV} / c^{2}$ to $\pm 5 \mathrm{MeV} / c^{2}$ of the nominal value depending on the decay mode.

We reconstruct a $B$ candidate by combining the $D^{(*)+}$ candidate with a $\pi^{-}$candidate satisfying $P(K / \pi)<0.8$,

corresponding to more than $90 \%$ efficiency for detecting pions and less than $10 \%$ probability for misidentifying kaons as pions. We identify $B$ decays based on requirements on the energy difference $\Delta E \equiv \sum_{i} E_{i}-E_{\text {beam }}$ and the beam-energy constrained mass $M_{\mathrm{bc}} \equiv$ $\sqrt{E_{\text {beam }}^{2}-\left(\sum_{i} \vec{p}_{i}\right)^{2}}$, where $E_{\text {beam }}$ is the beam energy, and $\vec{p}_{i}$ and $E_{i}$ are the momenta and energies of the daughters of the reconstructed $B$ meson candidate, all in the cms. We define a signal region in the $\Delta E-M_{\mathrm{bc}}$ plane of $5.27 \mathrm{GeV} / c^{2}<M_{\mathrm{bc}}<5.29 \mathrm{GeV} / c^{2} \quad$ and $\quad|\Delta E|<$ 0.045 GeV , corresponding to about $\pm 3 \sigma$ on each quantity. If more than one $B$ candidate is found in the same event, we select the one with best $D$ vertex quality. For the determination of background parameters, we use events in a sideband region defined by $M_{\mathrm{bc}}>5.2 \mathrm{GeV} / c^{2}$ and $-0.14 \mathrm{GeV}<\Delta E<0.20 \mathrm{GeV}$, excluding the signal region.

The $\Delta E$ and $M_{\mathrm{bc}}$ distributions for $D^{*} \pi$ and $D \pi$ candidates are shown in Fig. 2, together with the results of a twodimensional fit in the region of $-0.1 \mathrm{GeV}<\Delta E<$ 0.2 GeV and $5.2 \mathrm{GeV} / c^{2}<M_{\mathrm{bc}}<5.3 \mathrm{GeV} / c^{2}$. In the fit, the signal distributions are described by the sum of two Gaussians in $\Delta E$ and a Gaussian in $M_{\mathrm{bc}}$. The background distributions are parametrized by a first order polynomial in $\Delta E$ and an ARGUS function [15] in $M_{\mathrm{bc}}$. All parameters are set free in the fit. A study using MC events indicates the presence of "peaking background" that peaks in the signal $\Delta E-M_{\mathrm{bc}}$ region and amounts to $1.7 \%$ ( $0.7 \%$ ) of the $D^{*} \pi(D \pi)$ candidates, respectively. We treat this contribution as a part of the signal, and assign a systematic error to account for this.

## B. Flavor tagging

Charged leptons, pions, and kaons that are not associated with the reconstructed $D^{(*)} \pi$ decays are used to identify the flavor of the accompanying $B$ meson. The algorithm [16] produces two parameters for each event, $q$ and $r$,

FIG. 2. $\Delta E$ and $M_{\mathrm{bc}}$ distributions for $B^{0} \rightarrow D^{*-} \pi^{+}$candidates (a and b), and $B^{0} \rightarrow D^{-} \pi^{+}$candidates (c and d). Curves are the fit results. Hatched regions indicate the background components of the fits.
where $q=+1(q=-1)$ for a $B^{0}\left(\bar{B}^{0}\right)$ meson and $r$ is a quality factor ranging from 0 for no flavor discrimination to 1 for unambiguous flavor assignment. The algorithm uses the kinematical variables of the event and compares to those from a large number of MC events, and is used only to sort the data into six intervals of $r$ according to estimated flavor purity. More than $99.5 \%$ of the events are assigned nonzero values of $r$.

## C. Vertex measurement

The decay vertex of the $B \rightarrow D^{(*)} \pi$ candidate is fitted using the track information of the $D$ and $\pi$ (except the slow $\pi$ from $D^{*}$ decay). For the decay vertex of the tagging $B$ meson, the remaining well-reconstructed tracks in the event are used. Tracks that are consistent with $K_{S}^{0}$ decay are rejected. We impose the additional requirement that both signal-side and tagging-side vertices be consistent with the run-dependent IP profile that typically extends $2 \mu \mathrm{~m}$ vertically, $8 \mu \mathrm{~m}$ horizontally, and 3 mm along the $z$ direction. A tight IP constraint in the transverse plane enables the reconstruction of decay vertices even with a single track. However, a study using a MC sample shows that the nominal $\chi^{2}$ of the vertex reconstruction is strongly correlated with the distance from the IP to the reconstructed vertex due to this tight constraint. To avoid possible bias in the event selection due to this correlation, we introduce a quantity that only depends on the $z$ coordinate quantities [17];

$$
\begin{equation*}
\xi \equiv \frac{1}{2 n} \sum_{i}^{n}\left|\frac{z_{i}^{\text {after }}-z_{i}^{\text {before }}}{\epsilon_{i}^{\text {before }}}\right|^{2} \tag{3}
\end{equation*}
$$

where $n$ is the number of tracks, $z_{i}$ is the $z$ position of the point of closest approach of the $i$ th track to the beam line before and after the vertex fit, and $\epsilon_{i}^{\text {before }}$ is the measurement error of the $z$ before the vertex fit. This quantity is calculated for the signal- and tagging-side separately, only for cases with multiple tracks. We require $\xi<100$ to eliminate badly reconstructed vertices, which amount to $4 \%(2 \%)$ of the signal-side and $1 \%(1 \%)$ of the taggingside in the $D^{*} \pi$ and $D \pi$ modes, respectively.

The proper-time difference between the vertices $z_{\text {rec }}$ and $z_{\text {tag }}$ (measured along the beam line) of the fully reconstructed $B$ candidate and the tagging $B$ meson, respectively, is calculated as

$$
\begin{equation*}
\Delta t=\left(z_{\mathrm{rec}}-z_{\mathrm{tag}}\right) / \beta \gamma c \tag{4}
\end{equation*}
$$

where $\beta \gamma=0.425$ is the Lorentz boost factor of the center of mass frame at KEKB. After application of the event selection criteria and the requirement that both $B$ mesons have well defined vertices and $|\Delta t|<70 \mathrm{ps}\left(\sim 45 \tau_{B^{0}}\right)$, 31491 and 31725 candidates remain in the $D^{*} \pi$ and $D \pi$ modes, respectively. The signal fractions of the candidates after the flavor tagging and vertexing, which vary for different $r$ bins, are $89 \%$ for $D^{*} \pi$ and $83 \%$ for $D \pi$.

## D. $\Delta t$ fit

Unbinned maximum likelihood fits to the four time dependent decay rates are performed to extract $S^{+}$and $S^{-}$. We minimize $-2 \sum_{i} \ln \mathcal{L}_{i}$ where the likelihood for the $i$ th event is given by

$$
\begin{equation*}
\mathcal{L}_{i}=\left(1-f_{\mathrm{ol}}\right)\left[f_{\mathrm{sig}} P_{\mathrm{sig}}+\left(1-f_{\mathrm{sig}}\right) P_{\mathrm{bkg}}\right]+f_{\mathrm{ol}} P_{\mathrm{ol}} \tag{5}
\end{equation*}
$$

The signal fraction $f_{\text {sig }}$ is determined from the $\left(\Delta E-M_{\mathrm{bc}}\right)$ value of each event.

The signal $\Delta t$ distribution is given by

$$
\begin{align*}
P\left(q=-1, D^{(*) \pm} \pi^{\overline{+}}\right)= & \left(1-w_{-}\right) P\left(B^{0} \rightarrow D^{(*) \pm} \pi^{\overline{+}}\right) \\
& +w_{+} P\left(\bar{B}^{0} \rightarrow D^{(*) \pm} \pi^{\mp}\right) \tag{6}
\end{align*}
$$

for the $q=-1$ sample, and

$$
\begin{align*}
P\left(q=+1, D^{(*) \pm} \pi^{\mp}\right)= & \left(1-w_{+}\right) P\left(\bar{B}^{0} \rightarrow D^{(*) \pm} \pi^{\mp}\right) \\
& +w_{-} P\left(B^{0} \rightarrow D^{(*) \pm} \pi^{\mp}\right) \tag{7}
\end{align*}
$$

for the $q=+1$ sample. Here $w_{+}$and $w_{-}$are, respectively, the probabilities to incorrectly assign the flavor of tagging $B^{0}$ and $\bar{B}^{0}$ mesons (wrong tag fractions), and the decay rates are given by Eq. (1).

The corresponding background distribution is parametrized as a sum of a $\delta$-function component and an exponential component with lifetime $\tau_{\text {bkg }}$ :

$$
\begin{equation*}
\delta\left(\Delta t-\mu_{\mathrm{bkg}}^{\delta}\right)+\frac{\left(1-f_{\mathrm{bkg}}^{\delta}\right)}{2 \tau_{\mathrm{bkg}}} e^{-\left|\Delta t-\mu_{\mathrm{bkg}}^{\tau}\right| / \tau_{\mathrm{bkg}}} \tag{8}
\end{equation*}
$$

where $f_{\mathrm{bkg}}^{\delta}$ is the fraction of events contained in the $\delta$-function, $\mu_{\text {bkg }}^{\delta}$ and $\mu_{\text {bkg }}^{\tau}$ are the mean values of $\Delta t$ in the $\delta$-function and exponential components, respectively. These parameters are determined separately from a fit to the $\Delta t$ distribution in the $\Delta E-M_{\mathrm{bc}}$ sideband data for the $D^{*} \pi$ and $D \pi$ data samples, SVD1 and SVD2 data, and cases where the vertices are reconstructed using single track and multiple tracks. Typically, values of the background $\Delta t$ parameters are: $f_{\mathrm{bkg}}^{\delta} \approx 0.4, \tau_{\mathrm{bkg}} \approx 1.1 \mathrm{ps}$, $\mu_{\mathrm{bkg}}^{\tau} \approx-0.1 \mathrm{ps}$, and $\mu_{\mathrm{bkg}}^{\delta} \approx 0$.

A small number of events (order of $1 \%$ ) have poorly reconstructed vertices resulting in very broad $\Delta t$ distributions. We account for this outlier contribution by adding a Gaussian component $P_{\text {ol }}$ with a width and fraction determined from the $B$ lifetime analysis [17].

## E. $\Delta t$ resolution

The probability density functions (PDF) for the signal and background must be convolved with corresponding $\Delta t$ resolution functions, that are determined on an event-byevent basis using the estimated uncertainties on the $z$ vertex positions [17,18], in order to be compared with the data. The signal resolution function is a convolution of three contributions: resolution functions for vertex reconstruction, smearing due to nonprimary tracks ( $K_{S}^{0}$ and charm

TABLE I. Parameters describing tagging side $C P$ violation effect that are determined from the $D^{*} l \nu$ data sample.

| $r$ | $S_{\text {tag }}^{+}$ | $S_{\text {tag }}^{-}$ |
| :--- | :---: | :---: |
| $0.000-0.250$ | $-0.058 \pm 0.130$ | $+0.060 \pm 0.130$ |
| $0.250-0.500$ | $+0.001 \pm 0.040$ | $+0.018 \pm 0.040$ |
| $0.500-0.625$ | $+0.027 \pm 0.032$ | $-0.030 \pm 0.032$ |
| $0.625-0.750$ | $+0.026 \pm 0.025$ | $+0.022 \pm 0.025$ |
| $0.750-0.875$ | $-0.011 \pm 0.025$ | $+0.027 \pm 0.025$ |
| $0.875-1.000$ | $-0.005 \pm 0.014$ | $+0.024 \pm 0.014$ |

daughters), and the kinematic approximation that the $B$ mesons are at rest in the cms. The resolution function is described in detail elsewhere [17].

The background resolution function is parametrized as a sum of two Gaussians where different values are used for the parameters depending on whether or not both vertices are reconstructed with multiple tracks. These parameters are determined from the $\Delta E-M_{\mathrm{bc}}$ sideband data.

## F. Tagging side $\boldsymbol{C P}$ violation effect

While the tagging side should have no asymmetry if the flavor is tagged by primary leptons since semileptonic decays are flavor-specific processes, it is possible to introduce a small asymmetry when daughter particles of hadronic decays such as $D^{(*)} \boldsymbol{\pi}$ are used for the flavor tagging, due to the same $C P$ violating effect that is the subject of this paper [19]. This effect is taken into account by replacing the $S^{ \pm}$parameters in Eq. (1) by

$$
\begin{align*}
& B^{0} \rightarrow D^{(*)+} \pi^{-}: S^{+} \rightarrow\left(S^{+}-S_{\mathrm{tag}}^{+}\right) \\
& B^{0} \rightarrow D^{(*)-} \pi^{+}: S^{-} \rightarrow\left(S^{-}+S_{\mathrm{tag}}^{+}\right)  \tag{9}\\
& \bar{B}^{0} \rightarrow D^{(*)+} \pi^{-}: S^{+} \rightarrow\left(S^{+}+S_{\mathrm{tag}}^{-}\right), \\
& \bar{B}^{0} \rightarrow D^{(*)-} \pi^{+}: S^{-} \rightarrow\left(S^{-}-S_{\mathrm{tag}}^{-}\right),
\end{align*}
$$

respectively. Here $S_{\text {tag }}^{+}$and $S_{\text {tag }}^{-}$represent the $C P$ violation effect on the flavor tagging side due to the presence of $B^{0} \rightarrow \bar{D} \bar{X}$ and $\bar{B}^{0} \rightarrow D X$ amplitudes, respectively. Note that unlike the $S^{ \pm}$parameters, which are defined rigorously
in terms of $B^{0} \rightarrow D^{(*) \mp} \pi^{ \pm}$and $\bar{B}^{0} \rightarrow D^{(*) \pm} \pi^{\mp}$ amplitudes, $S_{\text {tag }}^{ \pm}$are effective quantities that include effects of the fraction of $B \rightarrow D X(\bar{D} \bar{X})$ components in the tagging $B$ decays and the subsequent behavior of $D(\bar{D})$ mesons. Therefore, these quantities must be determined experimentally.

The values of $S_{\text {tag }}^{ \pm}$are determined in each $r$ bin by fitting the $\Delta t$ distributions of a $B \rightarrow D^{*} l \nu$ control sample [16] using the signal PDFs of Eqs. (6) and (7) and setting $S^{ \pm}$to zero. Since the $D^{*} l \nu$ final states have specific flavor, any observable asymmetry must originate from the tagging side. The results, with statistical errors only, for each $r$ bin are listed in Table I. The result for the combined $r$ bins are $S_{\text {tag }}^{+}=-0.002 \pm 0.009 \pm 0.006$ and $S_{\text {tag }}^{-}=$ $0.017 \pm 0.009 \pm 0.006$, where the second errors are systematic. The systematic errors are estimated in a similar way to that described later for our main results-the largest contributions are from the signal $\Delta t$ resolution and wrong tag fraction.

## G. Fit result

The procedures for $\Delta t$ determination and flavor tagging are tested by extracting $\tau_{B^{0}}$ and $\Delta m$. When all four signal categories in Eq. (1) are combined, the signal $\Delta t$ distribution reduces to an exponential lifetime distribution as shown in Fig. 3(a). We do a simultaneous fit to the SVD1 and SVD2 samples by combining the $D^{*} \pi$ and $D \pi$ candidate events and obtain $\tau_{B^{0}}=1.532 \pm 0.013 \mathrm{ps}$, where the error is statistical only, in good agreement with the world average of $1.536 \pm 0.014 \mathrm{ps}$ [20]. Combining the two CFD-dominant modes (denoted as OF because the signal side and tagging side have opposite $B$ flavor) and the two mixing-dominant modes (denoted as SF because the signal side and tagging side have the same $B$ flavor) and ignoring the $C P$ violating terms, an asymmetry $(\mathrm{OF}-\mathrm{SF}) /(\mathrm{OF}+$ SF) behaves as $\cos (\Delta m \Delta t)$ as shown in Fig. 3(b). A similar fit to the one used for the lifetime determination gives $\Delta m=0.494 \pm 0.007 \mathrm{ps}^{-1}$, where the error is statistical only, also in good agreement with the world average $0.502 \pm 0.007 \mathrm{ps}^{-1}$ [20]. This fit is also used to determine

FIG. 3. (a) $\Delta t$ distribution for the signal candidates when all four signal categories are combined. (b) ( $\mathrm{OF}-\mathrm{SF}$ ) $/(\mathrm{OF}+\mathrm{SF})$ asymmetries. Curves are the fit results. The hatched region in (a) indicates the background.

TABLE II. Fit results for the wrong tag fractions of the SVD2 sample. They are determined in each $r$ bin as the averages and differences of the two flavors.

| $r$ | $\left(w_{+}+w_{-}\right) / 2$ | $\left(w_{+}-w_{-}\right)$ |
| :--- | :---: | :---: |
| $0.000-0.250$ | $0.461 \pm 0.006$ | $+0.001 \pm 0.009$ |
| $0.250-0.500$ | $0.327 \pm 0.009$ | $-0.026 \pm 0.013$ |
| $0.500-0.625$ | $0.216 \pm 0.010$ | $+0.032 \pm 0.015$ |
| $0.625-0.750$ | $0.163 \pm 0.009$ | $-0.001 \pm 0.014$ |
| $0.750-0.875$ | $0.124 \pm 0.009$ | $-0.020 \pm 0.014$ |
| $0.875-1.000$ | $0.032 \pm 0.005$ | $+0.012 \pm 0.009$ |

the signal $\Delta t$ resolution parameters and wrong tag fractions $w_{+}$and $w_{-}$in each $r$ bin for both the SVD1 and SVD2 samples. Table II lists the fit result for the wrong tag fractions in the SVD2 sample. Those from the SVD1 sample have very similar values.

We then perform fits to determine the values of $S^{ \pm}$by fixing $\tau_{B^{0}}$ and $\Delta m_{d}$ to the world average values and using previously determined $w_{ \pm}$and $S_{\text {tag }}^{ \pm}$in each $r$ bin. The results are $S^{+}\left(D^{*} \pi\right)=0.050 \pm 0.029, \quad S^{-}\left(D^{*} \pi\right)=$ $0.028 \pm 0.028, S^{+}(D \pi)=0.031 \pm 0.030$, and $S^{-}(D \pi)=$ $0.068 \pm 0.029$. The errors are statistical only.

The $\Delta t$ distributions for the subsamples having the best quality flavor tagging $(0.875<r \leq 1.0)$ are shown in Fig. 4 for the $D^{*} \pi$ mode and in Fig. 5 for the $D \pi$ mode. For both modes, this region constitutes roughly $14 \%$ of the total, but has significant statistical power for the $S^{ \pm}$ determination.

FIG. 4. $\Delta t$ distributions for the $D^{*} \pi$ events in the $0.875<r \leq 1.0$ flavor-tagging quality bin. (a) $B^{0} \rightarrow D^{*+} \pi^{-}$, (b) $B^{0} \rightarrow D^{*-} \pi^{+}$, (c) $\bar{B}^{0} \rightarrow D^{*+} \pi^{-}$, (d) $\bar{B}^{0} \rightarrow D^{*-} \pi^{+}$. Curves show the results of fits to the entire event sample, and hatched regions indicate the backgrounds.

FIG. 5. $\Delta t$ distributions for the $D \pi$ events in the $0.875<r \leq 1.0$ flavor-tagging quality bin. (a) $B^{0} \rightarrow D^{+} \pi^{-}$, (b) $B^{0} \rightarrow D^{-} \pi^{+}$, (c) $\bar{B}^{0} \rightarrow D^{+} \pi^{-}$, (d) $\bar{B}^{0} \rightarrow D^{-} \pi^{+}$. Curves show the results of fits to the entire event sample, and hatched regions indicate the backgrounds.
contributions from unknown effects in the vertex measurement such as the misalignment of the SVD and drift of the IP profile, we do not explicitly assign any additional error to the vertexing other than that from the $\xi$ cut.

We test for possible bias in the fitting procedure using $B \rightarrow D^{*} \pi$ and $B \rightarrow D^{*} l \nu$ MC samples. Neither MC sample includes $C P$ violation in the signal side nor in the tag side, so the fit should return zero $S^{ \pm}$values in principle. We first fit the $D^{*} l \nu$ sample and determine the $S_{\text {tag }}^{ \pm}$values. Using these values, we fit the $D^{*} \pi$ sample. The larger deviation of the obtained $S^{ \pm}$from zero is 0.008 . We repeat the $D^{*} \pi$ fit by setting $S_{\text {tag }}^{ \pm}=0$ and compare the obtained $S^{ \pm}$with the previous values. We obtain 0.010 as the larger difference. The latter study is intended to account for a possible additional fit bias that is introduced by including

TABLE III. Summary of the systematic errors in the $S^{ \pm}$measurements using the full reconstruction method.

| Sources | $D^{*} \pi$ | $D \pi$ |
| :--- | :---: | ---: |
| Signal $\Delta t$ resolution | 0.005 | 0.004 |
| Background $\Delta t$ shape | negligible | negligible |
| Background fraction | 0.002 | 0.001 |
| Wrong tag fraction | 0.002 | 0.002 |
| Vertexing | 0.004 | 0.002 |
| Physics parameters $\left(\Delta m, \tau_{B^{0}}\right)$ | 0.001 | 0.001 |
| Tag side asymmetry | 0.005 | 0.005 |
| Fit bias | 0.010 | 0.010 |
| Total | 0.013 | 0.012 |

the $S_{\text {tag }}$ parameters in the fit. We take 0.010 (larger of 0.008 and 0.010 ) as an estimate of the possible size of biases in the fitting procedure.

We obtain a total systematic error of 0.013 for $D^{*} \pi$ and 0.012 for $D \pi$. Table III summarizes the contributions to the systematic errors.

## I. Result

We obtain

$$
\begin{align*}
S^{+}\left(D^{*} \pi\right) & =0.050 \pm 0.029 \pm 0.013 \\
S^{-}\left(D^{*} \pi\right) & =0.028 \pm 0.028 \pm 0.013 \\
S^{+}(D \pi) & =0.031 \pm 0.030 \pm 0.012  \tag{10}\\
S^{-}(D \pi) & =0.068 \pm 0.029 \pm 0.012
\end{align*}
$$

from the full reconstruction method, where the first error is statistical and the second error is systematic.

## IV. PARTIAL RECONSTRUCTION ANALYSIS

## A. Signal event selection

Candidate events are selected by requiring the presence of fast pion and slow pion candidates. In order to obtain accurate vertex position determinations, fast pion candidates are required to have a radial (longitudinal) impact parameter $d r<0.1 \mathrm{~cm}(|d z|<2.0 \mathrm{~cm})$, to have associated hits in the SVD, and to have a polar angle in the laboratory frame in the range $30^{\circ}<\theta_{\text {lab }}<135^{\circ}$. The vertex positions
are obtained by fits of the candidate tracks with the IP. Fast pion candidates are required to be inconsistent with the lepton hypothesis (see below), and the kaon hypothesis, based on information from the CDC, TOF and ACC. A requirement on the fast pion cms momentum of $1.83 \mathrm{GeV} / c<p_{\pi_{f}}<2.43 \mathrm{GeV} / c$ is made; this range includes both signal and sideband regions (defined below). Slow pion candidates are required to have cms momentum in the range $0.05 \mathrm{GeV} / c<p_{\pi_{s}}<0.30 \mathrm{GeV} / c$. No requirement is made on particle identification for slow pions; since they are not used for vertexing, only a loose requirement that they originate from the IP is made. The fast and slow pion candidates must have opposite charges.

## B. Flavor tagging

In order to tag the flavor of the associated $B$ meson and to reduce background from continuum $e^{+} e^{-} \rightarrow q \bar{q}(q=$ $u, d, s, c$ ) processes, we require the presence of a highmomentum lepton in the event. Tagging lepton candidates are required to be positively identified either as electrons, on the basis of information from the CDC, ECL and ACC, or as muons, on the basis of information from the CDC and the KLM. They are required to have momentum in the range $1.2 \mathrm{GeV} / c<p_{l_{\text {tag }}}<2.3 \mathrm{GeV} / c$, and to have an angle with the fast pion candidate that satisfies $-0.75<$ $\cos \delta_{\pi_{f} l}$ in the cms. The lower bound on the momentum and the requirement on the angle also reduce, to a negligible level, the contribution of leptons produced from semileptonic decays of the unreconstructed $D$ mesons in the $B^{0} \rightarrow$ $D^{* \mp} \pi^{ \pm}$decay chain. No other tagging lepton candidate with momentum greater than $1.0 \mathrm{GeV} / c$ is allowed in the event to reduce the mistagging probability, and also to reduce the contribution from leptonic charmonium decays. Identical vertexing requirements to those for fast pion candidates are made in order to obtain an accurate $z_{\text {tag }}$ position. To further suppress the small remaining continuum background, we impose a loose requirement on the ratio of the second to zeroth Fox-Wolfram [21] moments, $R_{2}<0.6$.

## C. Kinematic fit

Signal events are distinguished from background using a set of three kinematic variables, which are denoted by $p_{\pi_{f}}$, $\cos \delta_{\pi_{f} \pi_{s}}$ and $\cos \theta_{\text {hel }}$. This set was chosen to minimize the correlation among variables, based on a study of Monte Carlo simulations. The cosine of the angle between the fast pion direction and the opposite of the slow pion direction in the $\mathrm{cms}, \cos \delta_{\pi_{f} \pi_{s}}$, peaks sharply at +1 for signal, as the slow pion follows the $D^{*}$ direction due to the small energy released in the $D^{*}$ decay. The cosine of the angle between the slow pion direction and the opposite of the $B$ direction in the $D^{*}$ rest frame, $\cos \theta_{\text {hel }}$, has a distribution proportional to $\cos \theta_{\text {hel }}^{2}$ for signal events, as the $B$
decay is a pseudoscalar to pseudoscalar vector transition. Since the $D^{*}$ is not fully reconstructed, $\cos \theta_{\text {hel }}$ is calculated using kinematic constraints on the decay of $B$ and $D^{*}$ mesons (see [6] for details). The background can populate the unphysical region $\left|\cos \theta_{\text {hel }}\right|>1$.

We select candidates that satisfy $1.93 \mathrm{GeV} / c<p_{\pi_{f}}<$ $2.43 \mathrm{GeV} / c, \quad 0.850<\cos \delta_{\pi_{f} \pi_{s}}<1.000$ and $-1.70<$ $\cos \theta_{\text {hel }}<1.80$. In the cases where more than one candidate satisfies these criteria, we select the one with the largest value of $\cos \delta_{\pi_{f} \pi_{s}}$. We further define signal regions in $p_{\pi_{f}}$ and $\cos \delta_{\pi_{f} \pi_{s}}$ as $2.13 \mathrm{GeV} / c<p_{\pi_{f}}<2.43 \mathrm{GeV} / c$, $0.925<\cos \delta_{\pi_{f} \pi_{s}}<1.000$, and two regions in $\cos \theta_{\mathrm{hel}}$ : $-1.00<\cos \theta_{\text {hel }}<-0.30$ and $+0.40<\cos \theta_{\text {hel }}<+1.10$.

Background events are separated into three categories: $D^{* \mp} \rho^{ \pm}$, which is kinematically similar to the signal; correlated background, in which the slow pion originates from the decay of a $D^{*}$ that in turn originates from the decay of the same $B$ candidate as the fast pion candidate (e.g., $D^{* *} \pi$ ); and uncorrelated background, which includes everything else (e.g., continuum processes, $D \pi$ ). The kinematic distributions of the background categories and the signal are determined from a large MC sample, corresponding to two times the integrated luminosity of our data sample, in which the branching fractions of the signal and major background sources are weighted according to the most recent knowledge [20,22]. We also use this MC sample for various tests of the analysis algorithms.

Event-by-event signal fractions are determined from binned maximum likelihood fits to the three-dimensional kinematic distributions ( 6 bins of $p_{\pi_{f}} \times 5$ bins of $\cos \delta_{\pi_{f} \pi_{s}} \times 10$ bins of $\cos \theta_{\text {hel }}$ ). The results of these fits, projected onto each of the three variables, are shown in Fig. 6, and summarized in Table IV.

## D. $\Delta \boldsymbol{t}$ fit procedure

In order to measure the $C P$ violation parameters in the $D^{*} \pi$ sample, we perform a simultaneous unbinned fit to the same-flavor (SF) events, in which the fast pion and the tagging lepton have the same charge, and opposite-flavor (OF) events, in which the fast pion and the tagging lepton have the opposite charge. We minimize the quantity $-2 \ln \mathcal{L}=-2 \sum_{i} \ln \mathcal{L}_{i}$, where

$$
\begin{equation*}
\mathcal{L}_{i}=f_{D^{*} \pi} P_{D^{*} \pi}+f_{D^{*} \rho} P_{D^{*} \rho}+f_{\text {unco }} P_{\text {unco }}+f_{\text {corr }} P_{\text {corr }} \tag{11}
\end{equation*}
$$

The event-by-event signal and background fractions (the $f$ terms) are taken from the results of the kinematic fits. Each $P$ term contains an underlying physics PDF, with experimental effects taken into account. For $D^{*} \pi$ and $D^{*} \rho$, the PDF is given by Eq. (1), where for $D^{*} \rho$ the terms $S^{ \pm}$ are effective parameters averaged over the helicity states [23] that are constrained to be zero. The PDF for correlated background contains a term for neutral $B$ decays [given by Eq. (1) with $\left.S^{ \pm}=0\right]$, and, in the case of OF events, a term

FIG. 6. Results of the kinematic fits to $D^{*} \pi$ candidates, projected onto (top) the $p_{\pi_{f}}$ axis, (middle) the $\cos \delta_{\pi_{f} \pi_{s}}$ axis and the (bottom) $\cos \theta_{\text {hel }}$ axis, in both (left) selection region and (right) signal region. The arrows show the edges of the signal regions.

TABLE IV. Summary of the results of the three-dimensional fits to kinematic variables. The numbers of events and fractions given for each category are those extrapolated to inside the signal regions in all three variables. The errors on the fractions are returned by the fit and propagated to the corresponding numbers of events.

|  | Candidates | Fraction |
| :--- | :---: | :---: |
| Data | $32844 \pm 181$ | - |
| $D^{*} \pi$ | $21741 \pm 217$ | $0.662 \pm 0.007$ |
| $D^{*} \rho$ | $2091 \pm 45$ | $0.064 \pm 0.001$ |
| Correlated background | $2703 \pm 42$ | $0.082 \pm 0.001$ |
| Uncorrelated background | $6287 \pm 40$ | $0.191 \pm 0.001$ |

for charged $B$ decays (for which the PDF is $\frac{1}{2 \tau_{B^{+}}} e^{-|\Delta t| / \tau_{B^{+}}}$, where $\tau_{B^{+}}$is the lifetime of the charged $B$ meson).

The PDF for uncorrelated background also contains neutral and charged $B$ components, with the remainder from continuum $e^{+} e^{-} \rightarrow q \bar{q}(q=u, d, s, c)$ processes. The continuum PDF is modeled with two components: one with negligible lifetime, and the other with a finite lifetime. The sideband parameters are determined from data sidebands, as described later.

As mentioned above, experimental effects need to be taken into account to obtain the $P$ terms of Eq. (11). Mistagging is taken into account using

$$
\begin{align*}
P\left(l_{\text {tag }}^{-}, \pi_{f}^{ \pm}\right)= & \left(1-w_{-}\right) P\left(B^{0} \rightarrow D^{* \mp} \pi^{ \pm}\right) \\
& +w_{+} P\left(\bar{B}^{0} \rightarrow D^{* \mp} \pi^{ \pm}\right) \\
P\left(l_{\text {tag }}^{+}, \pi_{f}^{ \pm}\right)= & \left(1-w_{+}\right) P\left(\bar{B}^{0} \rightarrow D^{* \mp} \pi^{ \pm}\right)  \tag{12}\\
& +w_{-} P\left(B^{0} \rightarrow D^{* \mp} \pi^{ \pm}\right)
\end{align*}
$$

where $w_{+}$and $w_{-}$are the wrong tag fractions, and are determined from the data as free parameters in the fit for $S^{ \pm}$. It should be noted that the $w_{+}$and $w_{-}$values used here are different from those used in the full reconstruction methods because the flavor-tagging methods differ in two cases.

The time difference $\Delta t$ is related to the measured quantity $\Delta z$ as described in Eq. (4), with an additional term due to possible offsets in the mean value of $\Delta z$,

$$
\begin{equation*}
\Delta t \longrightarrow \Delta t+\epsilon_{\Delta t} \simeq\left(\Delta z+\epsilon_{\Delta z}\right) / \beta \gamma c \tag{13}
\end{equation*}
$$

It is essential to allow nonzero values of $\epsilon$ since a small bias can mimic the effect of $C P$ violation:

$$
\begin{equation*}
\cos (\Delta m \Delta t) \rightarrow \cos (\Delta m \Delta t)-\Delta m \epsilon_{\Delta t} \sin (\Delta m \Delta t) \tag{14}
\end{equation*}
$$

A bias as small as $\epsilon_{\Delta z} \sim 1 \mu \mathrm{~m}$ can lead to sinelike terms as large as 0.01 , comparable to the expected size of the $C P$ violation effect. Because both vertex positions are obtained from single tracks, the partial reconstruction analysis is more susceptible to such biases. We allow separate offsets for each combination of fast pion and tagging lepton charges. We also apply a small correction to each measured vertex position to correct for a known bias due to the relative misalignment of the SVD and CDC in SVD1 data. This correction is dependent on the track charge, momentum and polar angle, measured in the laboratory frame. It is obtained by comparing the vertex positions calculated with the alignment constants used in the data, to those obtained with an improved set of alignment constants [24], which removes the observed bias. The alignment in SVD2 data was found to be comparable to that of the corrected SVD1 data. No additional correction was thus applied to SVD2 data.

## E. $\Delta t$ resolution

Resolution effects are taken into account in a way similar to our full reconstruction analysis. The algorithm includes components related to detector resolution, kinematic smearing and nonprimary tracks.

For correctly tagged signal events, both the fast pion and the tagging lepton originate directly from $B$ meson decays. Therefore we do not include any additional smearing due to nonprimary tracks in these events. Incorrectly tagged events, however, almost exclusively originate from secondary leptons. Furthermore, due to the kinematic constraints on the momentum of the fast pion, secondary tracks consist almost exclusively of wrong-tag leptons. Only uncorrelated background events contain a small amount of secondary pions, which also give the wrong flavor
information. In order to take this effect into account, the PDFs of incorrectly tagged events are convolved with an additional resolution component whose parameters are determined from MC simulations. Three different sets of parameters are used: one set for uncorrelated background in the uncorrelated background sideband, where the fast pion momentum cut is loosened; one set for uncorrelated background in the two other regions (signal region and correlated background sideband); one set for all other categories of events (signal, $D^{*} \rho$ and correlated background), which contain similar amounts of secondary leptons, and no secondary pions. Because of the aforementioned correlation between mistagging and nonprimary tracks, each of these sets are linked to different wrong-tag fractions $w_{ \pm}$.

The effect of the approximation that the $B$ mesons are at rest in the cms in Eq. (4) is taken into account [17]. We use a slightly modified algorithm to describe the detector resolution, in order to precisely describe the observed behavior for single track vertices. The resolution for each track is described by the sum of three Gaussian components, with a common mean of zero, and widths that are given by the measured vertex error for each track multiplied by different scale factors.

We measure the five parameters of the detector resolution function (three scale factors and two parameters giving the relative normalizations of the Gaussians) using $J / \psi \rightarrow$ $\mu^{+} \mu^{-}$candidates. These are selected using criteria similar to those for $D^{*} \pi$, except that both tracks are required to be identified as muons, and their invariant mass is required to be consistent with that of the $J / \psi$. Vertex positions are obtained independently for each track, in the same way as described above. The quantity $\Delta z=z_{\mu^{+}}-z_{\mu^{-}}$then describes the detector resolution, which is the convolution of the two vertex resolutions, since for $J / \psi \rightarrow \mu^{+} \mu^{-}$the underlying PDF is a delta function.

We perform an unbinned maximum likelihood fit using events in the $J / \psi$ signal region in the di-muon invariant mass, and using sideband regions to determine the shape of the background under the peak. The underlying $\Delta z$ PDF of the background is parametrized in the same way as that used for continuum, described above. Two sets of parameters are simultaneously determined for SVD1 and SVD2 data. We also take a possible offset into account, so that there are in total 16 free parameters in this fit (five describing the resolution function, two describing the background, and one $\Delta z$ offset, each for SVD1 and SVD2 data). The result is shown in Fig. 7.

## F. Background $\Delta t$ shape

The free parameters in the background PDFs $P_{\text {unco }}$ and $P_{\text {corr }}$ are determined using data from sideband regions. To measure the uncorrelated background shape, we use events in a sideband region of $-0.5<\cos \delta_{\pi_{f} \pi_{s}}<0.5$, which by definition is only populated by uncorrelated background,

FIG. 7. Result of the resolution parameter extraction procedure for $J / \psi \rightarrow \mu^{+} \mu^{-}$candidates selected from (top) SVD1 and (bottom) SVD2 data, shown with both (left) linear and (right) logarithmic coordinate scales. The data points show the $\Delta z$ distribution for candidates in the signal region; the full line shows the result of the fit. The dashed line indicates the background.
thus providing a very large sample to extract the various components of this background. We perform a simultaneous fit to OF and SF candidates, in both SVD1 and SVD2 data.

To obtain the correlated background parameters, a simultaneous fit is carried out to OF and SF events in a sideband region of $0.85<\cos \delta_{\pi_{f} \pi_{s}}<0.90$, $1.93 \mathrm{GeV} / c<p_{\pi_{f}}<2.13 \mathrm{GeV} / c$ and $-1.7<\cos \theta_{\text {hel }}<$ -0.3 . This sideband region is dominated by correlated and uncorrelated backgrounds-the contributions from $D^{*} \pi$ and $D^{*} \rho$ are found to be small in MC. The uncorrelated background parameters are fixed to the values found in the previous fit, except the $\Delta z$ offset (which are the same as that of correlated background) and the wrong tag fractions, as mentioned above.

## G. Fit result

In order to test our fit procedure, we first constrain $S^{+}$ and $S^{-}$to be zero and perform a fit in which $\tau_{B^{0}}$ and $\Delta m$ (as well as two wrong-tag fractions and eight offsets) are free parameters. We obtain $\tau_{B^{0}}=1.495 \pm 0.012 \mathrm{ps}$ and $\Delta m=0.506 \pm 0.006 \mathrm{ps}^{-1}$, where the errors are statistical only. These values are compatible with the current world averages [20]. Reasonable agreement with the input values is also obtained in MC. Furthermore, fits to the MC with $S^{ \pm}$floated give results consistent with zero, as expected.

To extract the $C P$ violation parameters we fix $\tau_{B^{0}}$ and $\Delta m$ at their world average values, and fit with $S^{+}, S^{-}$, two wrong-tag fractions and eight offsets as free parameters. We obtain $S^{+}=0.048 \pm 0.028$ and $S^{-}=0.034 \pm 0.027$
where the errors are statistical only. The wrong tag fractions are $w_{-}=(4.8 \pm 1.6) \%$ and $w_{+}=(3.4 \pm 1.6) \%$. All floating offsets are consistent with zero except the one for the $\pi^{-} \ell^{+}$combinations in the SVD1 sample. The results are shown in Fig. 8. To further illustrate the $C P$ violation effect, we define asymmetries in the same flavor events $\left(\mathcal{A}^{\mathrm{SF}}\right)$ and in the opposite flavor events $\left(\mathcal{A}^{\mathrm{OF}}\right)$, as

$$
\begin{align*}
\mathcal{A}^{\mathrm{SF}} & =\frac{N_{\pi^{-} l^{-}}(\Delta z)-N_{\pi^{+} l^{+}}(\Delta z)}{N_{\pi^{-} l^{-}}(\Delta z)+N_{\pi^{+} l^{+}}(\Delta z)}  \tag{15}\\
\mathcal{A}^{\mathrm{OF}} & =\frac{N_{\pi^{+} l^{-}}(\Delta z)-N_{\pi^{-} l^{+}}(\Delta z)}{N_{\pi^{+} l^{-}}(\Delta z)+N_{\pi^{-} l^{+}}(\Delta z)}
\end{align*}
$$

where the $N$ values indicate the number of events for each combination of fast pion and tag lepton charge. These are shown in Fig. 9. Note that due to the relative contributions of the sine terms in Eq. (1), vertex biases (i.e. nonzero offsets) can induce an opposite flavor asymmetry, whereas the same flavor asymmetry is more robust.

## H. Systematic error

Systematic errors due to the resolution function, the background fractions, the background parameters, and physics parameters are estimated by varying the values used in the fit by $\pm 1 \sigma$. Systematic effects due to differences between data and MC in the distributions used in the kinematic fit are further investigated by repeating the fit using different binning. We repeat the entire fit procedure using twice as many bins in each of the three discriminating variables. Since $\cos \delta_{\pi_{f} \pi_{s}}$ is used in the best candidate

FIG. 8. Results of the fit to obtain $S^{+}$and $S^{-}$. The fit result is superimposed on the data. The signal component is shown as the dashed line. The dotted line indicates the background contribution.
selection, we also repeat the algorithm without using this variable in the kinematic fit. The largest deviation (0.007) is assigned as a systematic error.

The resolution function parameters are precisely determined from the fit to $J / \psi \rightarrow \mu^{+} \mu^{-}$candidates. We consider systematic effects due to our lack of knowledge of the exact functional form of the resolution function: using different parametrizations results in shifts of $S^{ \pm}$as large as 0.008 , which we assign as a systematic error. Allowing for effective $S^{ \pm}$terms of $\pm 0.05$ in the $D^{*} \rho$ and correlated
background PDFs leads to systematic errors of 0.003 and 0.002 , respectively.

Vertex biases may lead to a large systematic error on $S^{ \pm}$, so we have introduced offsets to make our analysis relatively insensitive to such biases. These additional free parameters cause an increase in the statistical error of about $20 \%$. In order to estimate the systematic error due to these offsets, we compare the results in MC simulations with and without the offsets. A difference of +0.011 is found for $S^{+}$and is assigned as a systematic error for the

FIG. 9. Results of the fit to obtain $S^{+}$and $S^{-}$, shown as asymmetries in the (left) same flavor events and (right) opposite flavor events. The fit result is superimposed on the data.

TABLE V. Summary of the systematic errors in the $S^{ \pm}$measurements using the partial reconstruction method.

| Source | Error |
| :--- | ---: |
| Resolution fit | 0.002 |
| Resolution models | 0.008 |
| Kinematic smearing | 0.002 |
| Nonprimary tracks | 0.004 |
| Background shapes | negligible |
| Kinematic fit | 0.007 |
| $\tau_{B^{0}}, \Delta m$ | 0.001 |
| $C P$ violation in $D^{*} \rho$ and corr. bkgd. | 0.004 |
| Vertexing | 0.011 |
| Total | 0.017 |

offsets. We have further tested our fit routine for possible fit biases, such as could be caused by neglecting terms of $R_{D^{*} \pi}^{2}$ in the fit, by generating a number of large samples of signal MC with different input values of $S^{+}$and $S^{-}$. All results come out consistent with the input values, without evidence of any bias.

The systematic errors are summarized in Table V. The total systematic error (0.017) is obtained by adding the above terms in quadrature.

## I. Result

The results using the partial reconstruction method are

$$
\begin{align*}
& S^{+}=0.048 \pm 0.028 \pm 0.017 \\
& S^{-}=0.034 \pm 0.027 \pm 0.017 \tag{16}
\end{align*}
$$

where the first error is statistical and the second error is systematic.

## V. DISCUSSION

## A. Final results of $S^{ \pm}\left(D^{*} \pi\right)$ and $S^{ \pm}(D \pi)$

The $D^{*} \pi$ signal candidates in the full reconstruction sample and the partial reconstruction sample are mostly
independent. We find only $60 D^{*} \pi$ candidates which enter both samples. We repeat the analysis of the partial reconstruction sample after removing those overlapping candidates and obtain the same result. Therefore we combine the two results. Some part of the systematic errors in the two measurements may be correlated. We conservatively assume that contributions from physics parameters and fit biases (fit and MC bias in the full reconstruction sample and $\Delta z$ offsets in the partial reconstruction sample) in the two measurements are $100 \%$ correlated, and combine them by taking a weighted average using the inverse of the statistical errors as weights. The final results are

$$
\begin{align*}
& S^{+}\left(D^{*} \pi\right)=0.049 \pm 0.020 \pm 0.011 \\
& S^{-}\left(D^{*} \pi\right)=0.031 \pm 0.019 \pm 0.011  \tag{17}\\
& S^{+}(D \pi)=0.031 \pm 0.030 \pm 0.012 \\
& S^{-}(D \pi)=0.068 \pm 0.029 \pm 0.012
\end{align*}
$$

where the first errors are statistical and the second errors are systematic. These results are shown in Fig. 10 in terms of $1 \sigma, 2 \sigma$, and $3 \sigma$ allowed regions in the $S^{-}$versus $S^{+}$ space. Small possible correlations in the systematic errors of $S^{+}$and $S^{-}$are neglected.

The results for $D^{*} \pi$ and $D \pi$ decay modes show that the ( $S^{+}+S^{-}$) values are $2.5 \sigma$ and $2.2 \sigma$ away from zero while the $\left(S^{+}-S^{-}\right)$values are within $1 \sigma$ of zero. Since $\left(S^{+}+\right.$ $\left.S^{-}\right) \propto \sin \left(2 \phi_{1}+\phi_{3}\right) \cos \delta$ and $\left(S^{+}-S^{-}\right) \propto \cos \left(2 \phi_{1}+\right.$ $\left.\phi_{3}\right) \sin \delta$ [Eq. (2)], it can be seen that these results are consistent with both $\delta_{D^{*} \pi}$ and $\delta_{D \pi}$ being small, as predicted by some theoretical models [5]. The significance of $C P$ violation, seen as deviations of $\left(S^{+}+S^{-}\right)$from zero, is $2.5 \sigma$ for $D^{*} \pi$ and $2.2 \sigma$ for $D \pi$ decay modes.

## B. Constraints on $\left(2 \phi_{1}+\phi_{3}\right)$ and $R$

Since we have two measurements ( $S^{+}$and $S^{-}$) which depend on three unknowns ( $R, 2 \phi_{1}+\phi_{3}, \delta$ ), there is not sufficient information to solve for the weak phase ( $2 \phi_{1}+$ $\left.\phi_{3}\right)$. Instead we obtain exclusion regions in two-

FIG. 10 (color online). Results of the $S^{ \pm}$measurements expressed in terms of $S^{-}$vs $S^{+}$for the $D^{*} \pi$ (left) and $D \pi$ (right) modes. Shaded regions indicate allowed regions with $1 \sigma, 2 \sigma$ and $3 \sigma$ uncertainties defined by $\sqrt{-2 \ln \mathcal{L}}=1,4,9$, respectively

FIG. 11 (color online). Excluded regions of $\left(2 \phi_{1}+\phi_{3}\right)$ vs $R$ space at $1,2,3 \sigma$ level for the $D^{*} \pi$ (left) and $D \pi$ (right) decays. The range $0^{\circ}-180^{\circ}$ for $2 \phi_{1}+\phi_{3}$ is shown; there are additional solutions at $2 \phi_{1}+\phi_{3} \longrightarrow 2 \phi_{1}+\phi_{3}+180^{\circ}$.
dimensional space for any value of the third variable. The regions of $\left(2 \phi_{1}+\phi_{3}, R\right)$ space that are excluded at the 1 , 2, $3 \sigma$ levels are shown in Fig. 11. An alternative representation, shown in Fig. 12, gives the lower bound on $\left|\sin \left(2 \phi_{1}+\phi_{3}\right)\right|$ for any values of $R$ and $\delta$.

Further conclusions cannot be drawn without some theoretical estimate of the values of either $R_{D^{(*)} \pi}$ or $\delta_{D^{(+)} \pi}$. One interesting possibility is to estimate the size of $R_{D^{(*)} \pi}^{2}$ using decays such as $B^{+} \rightarrow D^{(*) \pm} \pi^{0}$ and $B^{0} \rightarrow$ $D_{s}^{(*) \pm} \pi^{\mp}$, which are related to $B^{0} \rightarrow D^{(*) \pm} \pi^{\mp}$ by isospin and $\mathrm{SU}(3)$, respectively [2].

The method using $S U(3)$ symmetry has some experimental advantages, since the rates are enhanced by the square of the tangent of the Cabibbo angle $\theta_{c}$. The relevant expression is

$$
\begin{equation*}
R_{D^{(*)} \pi}^{2}=\tan ^{2} \theta_{c}\left(\frac{f_{D^{(*)}}}{f_{D_{s}^{(*)}}}\right)^{2} \frac{\mathcal{B}\left(B^{0} \rightarrow D_{s}^{(*)+} \pi^{-}\right)}{\mathcal{B}\left(B^{0} \rightarrow D^{(*)-} \pi^{+}\right)} \tag{18}
\end{equation*}
$$

where $f_{M}$ is the decay constant for the $M$-meson. The
equality is valid up to $\mathrm{SU}(3)$ breaking effects. Both Belle [25] and $B A B A R$ [26] have reported evidence for the decay $B^{0} \rightarrow D_{s}^{+} \pi^{-}$. BABAR included a limit for the $B^{0} \rightarrow$ $D_{s}^{*+} \pi^{-}$mode in the same paper. We estimate $R_{D^{*} \pi}$ and $R_{D \pi}$ using the measured branching fractions and the form factors from a lattice QCD calculation by the UKQCD collaboration [27]. We use $\mathcal{B}\left(B^{0} \rightarrow D_{s}^{*+} \pi^{-}\right) / \mathcal{B}\left(B^{0} \rightarrow\right.$ $\left.D^{*-} \pi^{+}\right)=0.0068_{-0.0051}^{+0.0047}$, which is determined from the $B A B A R \quad$ result $\mathcal{B}\left(B^{0} \rightarrow D_{s}^{*+} \pi^{-}\right)=\left(1.9_{-1.3}^{+1.2} \pm 0.5\right) \times$ $10^{-5}$ and the PDG 2004 value $\mathcal{B}\left(B^{0} \rightarrow D^{*-} \pi^{+}\right)=$ $(2.76 \pm 0.21) \times 10^{-3}, \quad$ and $\quad \mathcal{B}\left(B^{0} \rightarrow D_{s}^{+} \pi^{-}\right) / \mathcal{B}\left(B^{0} \rightarrow\right.$ $\left.D^{-} \pi^{+}\right)=0.0098 \pm 0.0040$, which is determined from the PDG 2004 values of $\mathcal{B}\left(B^{0} \rightarrow D_{s}^{+} \pi^{-}\right)=(2.7 \pm 1.0) \times$ $10^{-5}$ and $\mathcal{B}\left(B^{0} \rightarrow D^{-} \pi^{+}\right)=(2.76 \pm 0.25) \times 10^{-3}$. The decay constant ratios are $f_{D^{*}} / f_{D_{s}^{*}}=1.04 \pm 0.01 \pm 0.02$ and $f_{D} / f_{D_{s}}=0.90 \pm 0.01 \pm 0.01$. We use $\tan \theta_{c}=0.23$ [20,28].

Adding $\pm 30 \%$ theory uncertainty for $\mathrm{SU}(3)$ breaking effects, such as contributions from annihilation diagrams, we obtain

FIG. 12 (color online). Lower limit on $\left|\sin \left(2 \phi_{1}+\phi_{3}\right)\right|$ as a function of $R$ at $1 \sigma(68 \% \mathrm{CL})$ (thin curves) and $2 \sigma$ (95\% CL) (thick curves) from (left) $D^{*} \pi$ and (right) $D \pi$. The estimated values for $R_{D^{(s)} \pi}$ are indicated as solid lines (central values). Coarse dotted lines and fine dotted lines indicate their $1 \sigma$ and $2 \sigma$ errors.

$$
\begin{align*}
& R_{D^{*} \pi}=0.020 \pm 0.007 \pm 0.006 \text { (theory) } \\
& R_{D \pi}=0.021 \pm 0.004 \pm 0.006 \text { (theory) } \tag{19}
\end{align*}
$$

as indicated in Fig. 12. If we use these values, we can restrict the allowed region of $\left|\sin \left(2 \phi_{1}+\phi_{3}\right)\right|$ to be

$$
\begin{equation*}
\left|\sin \left(2 \phi_{1}+\phi_{3}\right)\right|>0.44(0.13) \quad \text { at } 68 \%(95 \%) \mathrm{CL} \tag{20}
\end{equation*}
$$

from the results for the $D^{*} \pi$ mode and

$$
\begin{equation*}
\left|\sin \left(2 \phi_{1}+\phi_{3}\right)\right|>0.52(0.07) \quad \text { at } 68 \%(95 \%) \mathrm{CL} \tag{21}
\end{equation*}
$$

from the results for the $D \pi$ mode, respectively.

## VI. SUMMARY

We have measured $C P$ violation parameters that depend on $\phi_{3}$ using the time-dependent decay rates of the $B^{0} \rightarrow$ $D^{(*) \mp} \pi^{ \pm}$. A total of $386 \times 10^{6} B \bar{B}$ events were used in the analysis. While the $D \pi$ sample was collected by a standard full reconstruction method, the $D^{*} \pi$ sample was enlarged by using, in addition, a partial reconstruction technique, essentially doubling the statistical power of this mode.

The final results expressed in terms of $S^{+}$and $S^{-}$, which are related to the CKM angles $\phi_{1}$ and $\phi_{3}$, the ratio of suppressed to favored amplitudes, and the strong phase difference between them, as $S^{ \pm}=-R_{D^{*} \pi} \sin \left(2 \phi_{1}+\right.$ $\left.\phi_{3} \pm \delta_{D^{*} \pi}\right) /\left(1+R_{D^{*} \pi}^{2}\right) \quad$ for $\quad D^{*} \pi \quad$ and $\quad S^{ \pm}=$ $+R_{D \pi} \sin \left(2 \phi_{1}+\phi_{3} \pm \delta_{D \pi}\right) /\left(1+R_{D \pi}^{2}\right)$ for $D \pi$, are

$$
\begin{align*}
& S^{+}\left(D^{*} \pi\right)=0.049 \pm 0.020 \pm 0.011 \\
& S^{-}\left(D^{*} \pi\right)=0.031 \pm 0.019 \pm 0.011  \tag{22}\\
& S^{+}(D \pi)=0.031 \pm 0.030 \pm 0.012 \\
& S^{-}(D \pi)=0.068 \pm 0.029 \pm 0.012
\end{align*}
$$

where the first errors are statistical and the second errors
are systematic. These results are an indication of $C P$ violation in $B^{0} \rightarrow D^{*-} \pi^{+}$and $B^{0} \rightarrow D^{-} \pi^{+}$decays at the $2.5 \sigma$ and $2.2 \sigma$ levels, respectively. If we use the values of $R_{D^{*} \pi}$ and $R_{D \pi}$ that are determined using a combination of factorization and $\mathrm{SU}(3)$ symmetry assumptions, the branching fraction measurements for the $D_{s}^{(*)} \pi$ modes, and lattice QCD calculations, we obtain $68 \%$ ( $95 \%$ ) confidence level lower limits on $\left|\sin \left(2 \phi_{1}+\phi_{3}\right)\right|$ of 0.44 (0.13) and 0.52 (0.07) from the $D^{*} \pi$ and $D \pi$ modes, respectively.
